Fundamentals

Kapitel 1

Quantum Mechanics

Hierzu ist es notwendig, die Energy nicht als eine stetige unbeschränkt teilbare, sondern als eine discrete, aus einer ganzen Zahl von endlichen gleichen Teilen zusammengesetzte Grösse aufzufassen.

— Max Planck

1.1 Classical Mechanics

The formalism used in quantum mechanics largely stems from William Rowan Hamilton's formulation of classical mechanics. Through the process of canonical quantisation any classical model of a physical system is turned into a quantum mechanical model.

In Hamilton's formulation of classical mechanics, a complete description of a system of N particles is described by a set of canonical coordinates $q = (\vec{q}_1, \dots, \vec{q}_N)$ and corresponding conjugate momenta $p = (\vec{p}_1, \dots, \vec{p}_N)$. Together, each pair of coordinate and momentum form a point $\xi = (q, p)$ in phase space, which is a space of all possible states of the system. Moreover, pairs of generalised coordinates and conjugate momenta are canonical if they satisfy the Poisson brackets so that $\{q_i, p_k\} = \delta_{ij}$. The Poisson bracket of two functions is defined as

$$\{f, g\} = \frac{\partial f}{\partial q} \frac{\partial g}{\partial p} - \frac{\partial f}{\partial p} \frac{\partial g}{\partial q}. \quad (1.1)$$

The governing equations of motion in a classical system is Hamilton's equations,

$$\dot{q} = \frac{\partial}{\partial p} \mathcal{H}(q, p) \quad (1.2)$$

$$\dot{p} = -\frac{\partial}{\partial q} \mathcal{H}(q, p) \quad (1.3)$$

where $\mathcal{H}(q, p)$ is the Hamiltonian, a function for the total energy of the system. Hamilton's equations may also be stated in terms of the Poisson brackets,

$$\frac{dp_i}{dt} = \{p_i, \mathcal{H}\}, \quad \frac{dq_i}{dt} = \{q_i, \mathcal{H}\}. \quad (1.4)$$

A system consisting of N of equal mass m , subject forces caused by an external potential, as well as acting on each other with forces stemming from a central potential $w(q_{ij})$ has the following Hamiltonian,

$$\mathcal{H}(q, p) = \mathcal{T}(q) + \mathcal{V}(p) + \mathcal{W}(p) = \frac{1}{2m} \sum_i |\vec{p}_i|^2 + \sum_i v(\vec{r}_i) + \frac{1}{2} \sum_{i < j} w(\vec{r}_{ij}). \quad (1.5)$$

This Hamiltonian conveniently contains several parts - the kinetic energy, the external potential energy and the interaction energy; denoted by \mathcal{T} , \mathcal{V} and \mathcal{W} respectively.

1.2 Canonical Quantisation

In order to transition from a classical system to a quantum system, we move from the classical phase space to the Hilbert space, through the procedure known as canonical, or first¹-, quantisation. Whilst the state of a classical system is a point in phase space, a quantum state is a complex-valued state vector in discrete, infinite dimensional, Hilbert space, that is a complete vector space equipped with an inner product. This space is most commonly chosen to be the space of square-integrable functions Ψ , dependent on all coordinates

$$\Psi = \Psi(x_1, x_2, \dots, x_N). \quad (1.6)$$

These functions are dubbed wavefunctions and are maps from a point (x_1, \dots, x_N) in configuration space to the complex vector space,

$$\Psi : X^N \rightarrow \mathbb{C}. \quad (1.7)$$

It has been widely discussed how such an object can represent the state of a particle. The answer is provided by Max Born's probabilistic interpretation, which says that $|\Psi(x_1, \dots, x_N)|^2$, gives the probability of finding the particle at a certain position. For a situation with one particle in one dimension we have,

$$\int_a^b |\Psi(x)|^2 dx = \left\{ \begin{array}{l} \text{probability of finding the} \\ \text{particle between } a \text{ and } b \end{array} \right\} \quad (1.8)$$

while $|\Psi(x_1, x_2, \dots, x_N)|^2$ is the probability density for locating all particles at the point $(x_1, \dots, x_N) \in X^N$. Since the total probability must be 1, we are provided with a normalisation condition for the wavefunction,

$$\int_{X^N} |\Psi(x_1, x_2, \dots, x_N)|^2 dx_1 dx_2 \dots dx_N = 1. \quad (1.9)$$

1.2.1 The Dirac-von Neumann Postulates

The following postulates, or axioms, provide a precise and concise description of quantum mechanics in terms of operators on the Hilbert space. There are many variations of these postulates, introduced both by their namesakes Paul Adriene Maurice Dirac[12] and John von Neumann[41].

Hilbert Space A quantum state of an isolated physical system is described by a vector with unit norm in a Hilbert space, a complex vector space equipped with a scalar product.

¹Second quantisation comes later.

Observables Each physical observable of a system is associated with a *hermitian* operator acting on the Hilbert space. The eigenstates of each such operator define a *complete, orthonormal* set of vectors.

With \hat{O} an operator, hermiticity means,

$$\langle \phi | \hat{O} \psi \rangle = \langle \hat{O} \phi | \psi \rangle \equiv \langle \phi | \hat{O} | \psi \rangle. \quad (1.10)$$

Completeness means,

$$\sum_i |i\rangle \langle i| = \mathbf{1}. \quad (1.11)$$

Orthonormal means,

$$\langle i | j \rangle = \delta_{ij}. \quad (1.12)$$

Time Evolution The time evolution of the state vector, $|\psi\rangle = |\psi(t)\rangle$, is given by the Schrödinger equation².

$$i\hbar \frac{d}{dt} |\psi(t)\rangle = \hat{H} |\psi(t)\rangle. \quad (1.13)$$

Measurements Physically measurable values, associated with an observable \hat{O} are defined by the eigenvalues o_n of the observable,

$$\hat{O} |n\rangle = o_n |n\rangle. \quad (1.14)$$

The probability for finding a particular eigenvalue in the measurement is

$$p_n = |\langle n | \psi \rangle|^2, \quad (1.15)$$

with the system in state $|\psi\rangle$ before the measurement, and $|n\rangle$ as the eigenstate corresponding to the eigenvalue o_n .

1.3 The Many-Body Quantum Hamiltonian

The full Hamiltonian for a quantum many-body system can be a large and unwieldy thing. In this study we will constrain ourselves to the study of electronic systems. Purely on a phenomenological basis, one would include nuclear terms in the Hamiltonian as well. In this study however, we will stay within the Born-Oppenheimer approximation and treat the nuclei as stationary particles, thereby refraining from introducing terms that involve the motion of nuclei. Here we introduce the molecular electronic Breit-Pauli Hamiltonian, thoroughly described in Helgaker et al.[29],

$$\hat{H}_{\text{mol}}^{\text{BP}} = \begin{cases} \hat{H}_{\text{kin}} & \leftarrow \text{kinetic energy} \\ +\hat{H}_{\text{cou}} & \leftarrow \text{Coulomb interactions} \\ +\hat{H}_{\text{ee}} & \leftarrow \text{external electric field interaction} \\ +\hat{H}_Z & \leftarrow \text{Zeeman interactions} \\ +\hat{H}_{\text{so}} & \leftarrow \text{spin-orbit interactions} \\ +\hat{H}_{\text{ss}} & \leftarrow \text{spin-spin interactions} \\ +\hat{H}_{\text{oo}} & \leftarrow \text{spin-spin interactions} \\ +\hat{H}_{\text{dia}} & \leftarrow \alpha^4 \text{diamagnetic interactions} \end{cases} \quad (1.16)$$

²In the Schrödinger picture.

Kinetic energy The Breit-Pauli kinetic energy term in Equation 1.16 is

$$\hat{H}_{\text{kin}} = -\frac{1}{2} \sum_i \nabla_i^2 - \frac{\alpha^2}{8} \sum_i \nabla_i^4, \quad (1.17)$$

where the first term is the common classical kinetic energy operator and the second term is the relativistic mass-velocity term. This term arises because of the dependence of mass on velocity. This is one of the larger relativistic corrections for slow electrons. The mass-velocity term is unbounded from below and should not be included in variational calculations[35].

Coulomb interactions Coulomb interaction terms in the Breit-Pauli Hamiltonian (Equation 1.16) are the following,

$$\begin{aligned} \hat{H}_{\text{cou}} = & - \sum_{iK} \frac{Z_K}{r_{iK}} + \frac{1}{2} \sum_{i \neq j} \frac{1}{r_{ij}} + \frac{1}{2} \sum_{K \neq L} \frac{Z_K Z_L}{R_{KL}} \\ & + \frac{\alpha^2 \pi}{2} \sum_{iK} Z_K \delta(\mathbf{r}_{iK}) - \frac{\alpha^2 \pi}{2} \sum_{i \neq j} \delta(\mathbf{r}_{ij}) \\ & + \frac{2\pi}{3} \sum_{iK} Z_K R_K^2 \delta(\mathbf{r}_{iK}) - \frac{1}{3} \sum_{iK} \frac{\text{tr } \Theta_K (3\mathbf{r}_{iK} \mathbf{r}_{iK}^T - r_{iK}^2 I_3)}{r_{iK}^5}. \end{aligned} \quad (1.18)$$

The first three terms are the nonrelativistic Coulomb point-charge interactions between nucleus and electron, electron and electron and nucleus and nucleus, respectively. The fourth and fifth terms are the Darwin corrections caused by the Zitterbewegung of the electrons. Because the nuclear point-charge model is not always adequate, the second-to-last and last term correct errors from this approximation. Here, R_K is the nuclear extent and Θ_K is the nuclear quadrupole moment. These terms are important in nuclear resonance studies[35] and nuclear quadrupole resonance studies[1].

External electric field interactions The Breit-Pauli Hamiltonian includes terms that model the effects of an externally applied scalar potential $\phi(\mathbf{r})$,

$$\hat{H}_{\text{ef}} = - \sum_i \phi_i + \sum_K Z_K \phi_K + \frac{\alpha^2}{\phi_K} \sum_i (\nabla_i \cdot \mathbf{E}_i). \quad (1.19)$$

It is often safe to assume that the applied field are quite uniform on the molecular scale, and one therefore often expands Equation 1.19 in multipoles,

$$\hat{H}_{\text{ef}} = Q_{\text{tot}} \phi_0 - \mu_{\text{tot}} \cdot \mathbf{E}_0 - \frac{1}{2} \text{tr } \mathbf{Q}_{\text{tot}} \mathbf{V}_0 + \dots, \quad (1.20)$$

where q_{tot} is the total charge of the molecule, μ_0 is the dipole moment, \mathbf{Q}_{tot} is the second moment, and \mathbf{V}_0 is the electric field gradient. Higher-order terms are only necessary for fields that vary greatly in time.

Zeeman interactions Paramagnetic interactions of the molecule with an externally applied magnetic field \mathbf{B} are described by the Zeeman term in the Breit-Pauli Hamiltonian (Equation 1.16),

$$\hat{H}_Z = -\mathbf{B} \cdot \sum_i \left(-\frac{1}{2} \mathbf{l}_{iO} - \mathbf{s}_i + \frac{1}{2} \alpha^2 \mathbf{s}_i \nabla_i^2 \right) - \mathbf{B} \cdot \sum_K \mathbf{M}_K. \quad (1.21)$$

The nuclear part, here represented by the last term in Equation 1.21, are on the order of 10^{-3} in atomic units. This is much smaller than the electronic part, given by the first sum in

Equation 1.21, but the nuclear part is very important in nuclear magnetic resonance (NMR) computations, where it determines the unshielded resonance lines in the spectra.

The first term inside the parenthesis in Equation 1.21 corresponds to Zeeman interaction with the magnetic moment generated by the orbital angular momentum of the electrons, $\mathbf{l}_{iO} = \mathbf{r}_{iO} \times \mathbf{p}_i$. The second and third terms in the parenthesis are electronic contributions to Zeeman effect from the spin of the electrons. The relativistic correction constituted in the third term is important in electron paramagnetic resonance (EPR) spectroscopy.

Spin-orbit interactions Up to second order in the fine-structure constant, the terms that couple motion of electrons to particle spins in Equation 1.16 are

$$\begin{aligned} \hat{H}_{so} = & \frac{\alpha^2}{2} \sum_{iK} \frac{Z_K \mathbf{s}_i \cdot \mathbf{l}_{iK}}{r_{iK}^3} - \frac{\alpha^2}{2} \sum_{i \neq j} \frac{\mathbf{s}_i \mathbf{l}_{ij}}{r_{ij}^3} - \alpha^2 \sum_{i \neq j} \frac{\mathbf{s}_j \mathbf{l}_{ij}}{r_{ij}^3} \\ & + \alpha^2 \sum_{iK} \frac{\mathbf{M}_K \cdot \mathbf{l}_{iK}}{r_{iK}^3} + \frac{\alpha^2}{4} \sum_i (\mathbf{E}_i \times \mathbf{p}_i - \mathbf{p}_i \times \mathbf{E}_i) \end{aligned} \quad (1.22)$$

When electron spin coupled to magnetic field induced by other charges in motion we have spin-orbit interaction. The first term in Equation 1.22 models nuclear spin-orbit effect, the second term models interaction between the spin of a particle with its own orbit, the third is interaction with other orbits. The fourth term is known as the orbital hyperfine operator and couples magnetic moments to the orbital motion of electrons, while the fifth and last term is models coupling of electric fields and orbits.

Spin-spin interaction All terms that arise in the Breit-Pauli Hamiltonian (Equation 1.16) due to coupling between magnetic momenta or spin of two particles are

$$\begin{aligned} \hat{H}_{ss} = & \frac{\alpha^2}{2} \sum_{i \neq j} \left[\frac{r_{ij}^2 \mathbf{s}_i \cdot \mathbf{s}_j - 3 \mathbf{s}_i \cdot \mathbf{r}_{ij} \mathbf{r}_{ij} \cdot \mathbf{s}_j}{r_{ij}^5} - \frac{8\pi}{3} \delta(\mathbf{r}_{ij}) \mathbf{s}_i \cdot \mathbf{s}_j \right] \\ = & \alpha^2 \sum_{iK} \left[\frac{r_{iK}^2 \mathbf{s}_i \cdot \mathbf{M}_K - 3 \mathbf{s}_i \cdot \mathbf{r}_{iK} \mathbf{r}_{iK} \cdot \mathbf{M}_K}{r_{iK}^5} - \frac{8\pi}{3} \delta(\mathbf{r}_{iK}) \mathbf{s}_i \cdot \mathbf{M}_K \right] \\ = & \frac{\alpha^2}{2} \sum_{K \neq L} \left[\frac{r_{KL}^2 (\mathbf{M}_K \mathbf{M}_L - 3(\mathbf{M}_K \cdot \mathbf{R}_{KL})(\mathbf{R}_{KL} \cdot \mathbf{M}_L))}{R_{KL}^5} \right] \end{aligned} \quad (1.23)$$

Diamagnetic Interactions The magnitude of effects from diamagnetic interaction in the Breit-Pauli Hamiltonian (Equation 1.16) are terms of order α^4 or smaller. Most of these effects are only important in some cases where strong external magnetic fields are applied (NMR, EPR).

1.3.1 Atomic Units

In the Hamiltonian above (Equation 1.16), we have grown up and set $\hbar = m_e = e = \dots = 1$. This is a result of using atomic units, a form of commonly used dimensionless units. To see how these units arise, consider the time-independent Schrödinger equation for a Hydrogen atom,

$$\left(-\frac{\hbar^2}{2m_e} \nabla^2 - \frac{e^2}{4\pi\epsilon_0 r} \right) \phi = E\phi, \quad (1.24)$$

where \hbar is the reduced Planck constant, equal to Planck's constant divided by 2π ; m_e is the mass of the electron, $-e$ is the charge of the electron and ϵ_0 is the permittivity of free space. We make this equation dimensionless by letting $r \rightarrow \lambda r'$,

Tabelle 1.1: Conversion of atomic units to SI units.

Physical quantity	Conversion factor	Value
Length	a_0	$5.2918 \times 10^{-11} m$
Mass	m_e	$9.1095 \times 10^{-31} kg$
Time	\hbar/E_a	$2.4189 \times 10^{-17} s$
Charge	e	$1.6022 \times 10^{-19} C$
Energy	E_a	$4.3598 \times 10^{-18} J$
Velocity	$a_0 E_a / \hbar$	$2.1877 \times 10^6 m s^{-1}$
Angular momentum	\hbar	$1.0546 \times 10^{-34} J s$
Electric dipole moment	$e a_0$	$8.4784 \times 10^{-30} C m$
Electric polarizability	$e^2 a_0^2 / E_a$	$1.6488 \times 10^{-41} C^2 m^2 J^{-1}$
Electric field	$E_a / (e a_0)$	$5.1423 \times 10^{11} V m^{-1}$
Wave function	$a_0^{-3/2}$	$2.5978 \times 10^{15} m^{-3/2}$

$$\left(-\frac{\hbar^2}{2m_e \lambda^2} \nabla'^2 - \frac{e^2}{4\pi\epsilon_0 \lambda r'} \right) \phi' = E \phi'. \quad (1.25)$$

We can factor out the constants in front of the operators, if we choose λ so that,

$$\frac{\hbar^2}{m_e \lambda^2} = \frac{e^2}{4\pi\epsilon_0 \lambda} = E_a \rightarrow \lambda \frac{4\pi\epsilon_0 \hbar^2}{m_e e^2} = a_0 \quad (1.26)$$

where E_a is the atomic unit of energy that chemists call Hartree. Incidentally, we see that λ is just the Bohr radius, a_0 . If we let $E' = E/E_a$, we obtain the dimensionless Schrödinger equation,

$$\left(-\frac{1}{2} \nabla'^2 - \frac{1}{r'} \right) \phi' = E' \phi'. \quad (1.27)$$

Some conversion factors between atomic units and SI units can be found in Table 1.1.

1.4 Indistinguishable Particles

In classical mechanics, although particles are indistinguishable, one typically regards particles as individuals because a permutation of particles is counted as a new arrangement and something different than the initial configuration. This was called “Transcendental Individuality” by Heinz Post[46]. In quantum mechanics, on the other hand, a permutation is not regarded as giving rise to a new arrangement. It follows that quantum objects are very different from anything else we know from everyday life, and must be considered “non-individual”. By taken this idea to it’s extreme one may postulate that all particles of a given type are one and the same. Here from a telephone call between John Wheeler and Richard Feynman[13],

I received a telephone call one day at the graduate college at Princeton from Professor Wheeler, in which he said, “Feynman, I know why all electrons have the same charge and the same mass” “Why?” “Because, they are all the same electron!”

Following the brief discussion above one may conclude that, the probability density for the location of particles in a system must be permutation invariant,

$$|\Psi(x_1, x_2, \dots, x_i, x_j, \dots, x_N)|^2 = |\Psi(x_1, x_2, \dots, x_j, x_i, \dots, x_N)|^2. \quad (1.28)$$

For any arbitrary permutation, this is equivalent to

$$\Psi(x_1, \dots, x_N) = e^{i\alpha(\sigma)} \Psi(x_{\sigma(1)}, x_{\sigma(2)}, \dots, x_{\sigma(N)}), \quad (1.29)$$

where $\sigma \in S_N$ is some permutation of N indices and α is some real number that may be dependent on σ . The same relation can be written by way of a linear permutation operator,

$$(\hat{P}_\sigma \Psi)(x_1, \dots, x_N) = \Psi(x_{\sigma(1)}, x_{\sigma(2)}, \dots, x_{\sigma(N)}). \quad (1.30)$$

The ‘indistinguishability postulate’ states that if a permutation P is applied to a state representing an assembly of particles, there is no way of distinguishing between the permuted state and the original, by means of an observation at any time.

One can show (Difficult to show? exercise 2.2 in FYS-KJM4480) that

$$\hat{P}_\sigma \Psi = \begin{cases} \Psi \\ (-1)^{|\sigma|} \Psi \end{cases} \quad \forall \sigma \in S_N \quad (1.31)$$

where $|\sigma|$ is the number of transpositions in σ and the sign will be $(-1)^{|\sigma|} = \pm 1$. In the former case, when the sign is $+$, the wavefunction is “totally symmetric with respect to permutations”; while in the latter case, when the sign is $-$, the wavefunction is “totally anti-symmetric.”

This leads us to another postulate in quantum theory that we have only two types of basic particles, *bosons* have totally symmetric wavefunctions only, while *fermions* have totally anti-symmetric wavefunctions only. “The physical consequences of this postulate seems to be in good agreement with experimental data” [37]. Moreover, all particles with integer spin are bosons, and all particles with half-integer spin are fermions [15, 44]. This can be proved in relativistic quantum mechanics, but must be accepted as an axiom in nonrelativistic theory[30]. Boson follow Bose-Einstein statistics and fermions follow Fermi-Dirac statistics.

To this day, particles with no other spin has been found, but norwegian physicists Jon Magne Leinaas and Jan Myrheim discovered that in one- and two dimensions, more general permutations symmetries are possible. The dubbed this third class of fundamental particles anyons"[37].

1.5 Representation of the Wavefunction

We have already invested some time in what the wave-function is, but some more time is necessary in order to build a nomenclature for writing down wavefunctions that actually describe many-electron systems with which we are concerned. For some smaller systems it can be satisfactory or even provident to use a single, special function to describe the entire system. Here however, we introduce the Slater determinant as we will only consider many-electron wavefunctions that can be written as a single Slater determinant or as a linear combination of several Slater determinants.

We define an *orbital*³ which is the wavefunction for a single particle, or more precicely a single electron. The wavefunction a larger group of electrons, for instance those electrons surround an atom or molecule, we call the *molecular orbital*. We also discriminate between spatial orbitals which are functions of spatial coordinates; and spinorbitals, which are functions of the space and spin coordinates (typically a product of a spatial orbital and a spin function). A very complete description and thorough discussion of all things concerning electronic sructure wavefunctions is given by Szabo and Ostlund[56].

³Sometimes also called a single-particle function, a single-particle orbital, a single-electron orbital or similar. There is a chance that these terms will be used interchangeably throughout this text without warning.

1.5.1 Slater Determinants

The best description for a multiple-electron wavefunction, given by the independent-particle approximation is the Slater determinant,

$$\Phi = \frac{1}{\sqrt{N!}} \begin{vmatrix} \psi_1(1) & \psi_2(1) & \dots & \psi_N(1) \\ \psi_1(2) & \psi_2(2) & \dots & \psi_N(2) \\ \vdots & \vdots & \ddots & \vdots \\ \psi_1(N) & \psi_2(N) & \dots & \psi_N(N) \end{vmatrix} = \mathcal{A}\psi_1\psi_2\dots\psi_N, \quad (1.32)$$

where $\psi_i(\mu)$ is a spinorbital and \mathcal{A} is the antisymmetriser. The spinorbitals, are single-particle functions in $L^2(X)$, not necessarily orthonormal.

To illustrate why this is a good approximation of the electronic wave function, consider first the two-electron case,

$$\Phi_{N=2} = \frac{1}{\sqrt{(2)}}(\psi_1(1)\psi_2(2) - \psi_1(2)\psi_2(1)). \quad (1.33)$$

We see from this relatively simple expression that if the electrons where to occupy the same state. This ensures that the Pauli exclusion principle for fermions[45]. Moreover, if we switch coordinates of any two single-particle functions (spinorbitals), corresponding to the interchange of rows in Equation 1.32, the result is a change of sign. This attribute accomodates the total anti-symmetry necessary for a fermionic wavefunction.

Kapitel 2

Second Quantisation

Some Slater determinant is written,

$$|\Phi\rangle = |\phi_i \phi_j \phi_k \dots \phi_z\rangle = |ijk \dots z\rangle. \quad (2.1)$$

2.1 Creation and Annihilation Operators

The notation of creation and annihilation operators vary,

$$\begin{aligned} &\text{creation operator for spinorbital } \phi_i, \hat{X}_i^\dagger, \hat{a}_i^\dagger, \hat{c}_i^\dagger, \hat{i}^\dagger; \\ &\text{annihilation operator for spinorbital } \phi_i, \hat{X}_i, \hat{a}_i, \hat{c}_i, \hat{i}. \end{aligned}$$

Herein, \hat{a}_i^\dagger , \hat{a}_i is used and, if there is no change of confusion, \hat{i}^\dagger , \hat{i} .

The Creation Operator . For every single-particle index q , we define the creation operator \hat{c}_q^\dagger acting on the vacuum state by

$$\hat{a}_i^\dagger |0\rangle = |q\rangle. \quad (2.2)$$

For any slater determinant with $N > 0$, the action is defined by

$$\hat{a}_i^\dagger |jk \dots z\rangle = |ijk \dots z\rangle, \quad (2.3)$$

$$\hat{a}_i^\dagger |ijk \dots z\rangle = 0 \quad (2.4)$$

The Annihilation Operator . It is sufficient to state that the annihilation \hat{c}_i operator is the hermitian adjoint of the creation operator \hat{c}_i^\dagger , but to specify we have

$$\hat{a}_i |0\rangle = 0, \quad (2.5)$$

as there is no particle in the vacuum state to annihilate.

For any arbitrary Slater determinant, we have

$$\hat{a}_i |ijk \dots z\rangle = |ij \dots z\rangle, \quad (2.6)$$

$$\hat{a}_i |jk \dots z\rangle = 0 \quad (2.7)$$

SOMETHING MORE ABOUT THE DIFFERENT PERMUTATIONS.

We can now build a Slater determinant as the result of successive operation of several creation operators \hat{a}_q^\dagger on the vacuum state,

$$\hat{a}_i^\dagger \hat{a}_j^\dagger \hat{a}_k^\dagger \dots \hat{a}_z^\dagger |0\rangle = |ijk \dots z\rangle. \quad (2.8)$$

It is convenient to arrange the spinorbitals in a Slater determinant in alphabetical order, as in Equation 2.8. This makes it necessary to ascertain the effects a creation or annihilation operator will have on a Slater determinant when the affected orbital is not at the beginning of the string of orbitals in the Slater determinant. Generally we have,

$$\hat{P} |ijk \dots z\rangle = (-1)^{\sigma(\hat{P})} |ijk \dots z\rangle, \quad (2.9)$$

where \hat{P} permutes the string of orbitals and $\sigma(\hat{P})$ is the parity of the permutation \hat{P} . we have

$$\hat{a}_p^\dagger |ijk \dots z\rangle = (-1)^{\eta_p} |ijk \dots p \dots z\rangle, \quad (2.10)$$

$$\hat{a}_p |ijk \dots p \dots z\rangle = (-1)^{\eta_p} |ijk \dots z\rangle, \quad (2.11)$$

where η_p is the number of orbitals preceeding the orbital ϕ_p , pertaining to the creation (annihilation) operator, in the Slater determinant.

2.2 Anticommutator Relations

Consider some creation operators acting on a Slater determinant,

$$\begin{aligned} \hat{a}_p^\dagger \hat{a}_q^\dagger |ijk \dots\rangle &= |pqijk \dots\rangle \\ \hat{a}_q^\dagger \hat{a}_p^\dagger |ijk \dots\rangle &= |qpijk \dots\rangle = -|pqijk \dots\rangle. \end{aligned} \quad (2.12)$$

We demand that these two operations be equivalent, or that

$$\begin{aligned} \hat{a}_p^\dagger \hat{a}_q^\dagger &= -\hat{a}_q^\dagger \hat{a}_p^\dagger \\ \{\hat{a}_p^\dagger, \hat{a}_q^\dagger\} &\equiv \hat{a}_p^\dagger \hat{a}_q^\dagger + \hat{a}_q^\dagger \hat{a}_p^\dagger = \hat{0}. \end{aligned} \quad (2.13)$$

This is one of several important anti-commutator relations for creation and annihilation operators.

Similarly, for annihilation operators we have

$$\begin{aligned} \hat{a}_p \hat{a}_q |qpijk \dots\rangle &= \hat{a}_p |pijk \dots\rangle = |ijk \dots\rangle \\ \hat{a}_q \hat{a}_p |qpijk \dots\rangle &= -\hat{a}_q \hat{a}_p |pqijk \dots\rangle = -\hat{a}_q |qijk \dots\rangle = -|ijk \dots\rangle. \end{aligned} \quad (2.14)$$

These two operations must also be equivalent,

$$\begin{aligned} \hat{a}_p \hat{a}_q &= -\hat{a}_q \hat{a}_p \\ \{\hat{a}_p, \hat{a}_q\} &\equiv \hat{a}_p \hat{a}_q + \hat{a}_q \hat{a}_p = \hat{0}. \end{aligned} \quad (2.15)$$

One case remains, when a creation operator and an annihilation operator is applied together on a Slater determinant,

$$\hat{a}_p^\dagger \hat{a}_q |qijk \dots\rangle = \hat{a}_p^\dagger |ijk \dots\rangle = |pijk \dots\rangle. \quad (2.16)$$

This operation will replace ϕ_q by ϕ_p even if ϕ_p would have been somewhere else in the interior of the Slater determinant. Any sign change as an effect of moving the orbital to the front of the string would be negated when the orbital is moved back to the original position. Exchanging the order of the operators however,

$$\hat{a}_q \hat{a}_p^\dagger |qijk \dots\rangle = \hat{a}_q |pqijk \dots\rangle = -\hat{a}_q |qpijk \dots\rangle = -|pijk \dots\rangle. \quad (2.17)$$

We again see a sign change and have,

$$\{\hat{a}_p^\dagger, \hat{a}_q\} = \hat{0} \quad (p \neq q). \quad (2.18)$$

If, on the other hand, $p = q$ we have

$$\begin{aligned}\hat{a}_p^\dagger \hat{a}_p |p i j k \dots\rangle &= |p i j k \dots\rangle, \\ \hat{a}_p \hat{a}_p^\dagger |p i j k \dots\rangle &= 0,\end{aligned}\tag{2.19}$$

and if the orbital ϕ_p in question does not appear in the Slater determinant,

$$\begin{aligned}\hat{a}_p^\dagger \hat{a}_p |i j k \dots\rangle &= 0, \\ \hat{a}_p \hat{a}_p^\dagger |i j k \dots\rangle &= \hat{a}_p |p i j k \dots\rangle = |i j k \dots\rangle.\end{aligned}\tag{2.20}$$

For all cases we have that,

$$(\hat{a}_p^\dagger \hat{a}_p + \hat{a}_p \hat{a}_p^\dagger) |\dots\rangle = |\dots\rangle,\tag{2.21}$$

or

$$\{\hat{a}_p^\dagger, \hat{a}_p\} = \{\hat{a}_p, \hat{a}_p^\dagger\} = \hat{1}.\tag{2.22}$$

In conclusion, the anti-commutator relations of the creation and annihilation operators are,

$$\{\hat{a}_p, \hat{a}_q\} = \hat{0},\tag{2.23}$$

$$\{\hat{a}_p^\dagger, \hat{a}_q^\dagger\} = \hat{0},\tag{2.24}$$

$$\{\hat{a}_p^\dagger, \hat{a}_q\} = \{\hat{a}_p, \hat{a}_q^\dagger\} = \hat{\delta}_{pq}.\tag{2.25}$$

2.3 Representation of Operators

A second-quantised one-body operator is written like

$$\hat{h} = \sum_{i=1}^N \hat{h}(i) = \sum_{ij} \langle i | \hat{h} | j \rangle \hat{a}_i^\dagger \hat{a}_j,\tag{2.26}$$

where in general, $\langle p | \hat{h} | q \rangle$ is the matrix element of the single-particle operator \hat{h} in a given one-particle basis,

$$\langle p | \hat{h} | q \rangle = \int dx \phi_p(x)^* \hat{h} \phi_q(x).\tag{2.27}$$

More accurately, we see from Equation 2.26, that \hat{h} weighs each occupied orbital of a Slater determinant with the appropriate matrix element.

A second-quantised two-body operator is written like

$$\hat{w} = \sum_{i,j} \hat{w}(i,j) = \frac{1}{2} \sum_{ijkl} \langle ij | \hat{w} | kl \rangle \hat{a}_i^\dagger \hat{a}_j^\dagger \hat{a}_l \hat{a}_k = \frac{1}{4} \sum_{ijkl} \langle ij | kl \rangle \hat{a}_i^\dagger \hat{a}_j^\dagger \hat{a}_l \hat{a}_k,\tag{2.28}$$

where

$$\langle ij | \hat{w} | kl \rangle \equiv \langle i(1)j(2) | \hat{w}_{12} | k(1)l(2) \rangle\tag{2.29}$$

and the antisymmetric two-electron integral for \hat{u} is abbreviated,

$$\langle ij | \hat{w} | kl \rangle - \langle ij | \hat{w} | kl \rangle = \langle ij | \hat{w} | kl \rangle \equiv \langle ij | kl \rangle.\tag{2.30}$$

Similarly to the one-particle operator, the two-particle operator assigns the correct matrix element to pairs of single particle functions.

The second-quantised Hamiltonian can therefore be written,

$$\hat{H} = \hat{h} + \hat{w} = \sum_{ij} \hat{h}_{ij} \hat{a}_i^\dagger \hat{a}_j + \frac{1}{4} \sum_{ijkl} \langle ij | kl \rangle \hat{a}_i^\dagger \hat{a}_j^\dagger \hat{a}_l \hat{a}_k.\tag{2.31}$$

2.4 Normal Order and Wick's Theorem

We have built the foundations necessary to describe wavefunctions in terms of creation- and annihilation operators as well as a simple way of writing a general electronic Hamiltonian in the second-quantised manner. The following is a necessity to be able to compute vacuum expectation values ($\langle - | \hat{A}\hat{B} \dots | - \rangle$) of products of creation- and annihilation operators. Such expectation values are very important for several computational methods, see Harris, Monkhorst and Freeman (1992)[20].

2.4.1 Normal ordering and contractions

The normal-ordered product of a string of operators $\hat{A}_1, \hat{A}_2, \hat{A}_3, \dots$, is defined as the rearranged product of operators such that all the creation operators are the left of all the annihilation operators, including a phase factor corresponding to the parity of the permutation producing the rearrangement

$$\begin{aligned} n[\hat{A}_1 \hat{A}_2 \dots \hat{A}_n] &\equiv (-1)^{|\sigma|} \hat{A}_{\sigma(1)} \hat{A}_{\sigma(2)} \dots \hat{A}_{\sigma(n)} \\ &= (-1)^{\sigma(\hat{P})} \hat{P}(\hat{A}_1 \hat{A}_2 \dots \hat{A}_n) \\ &= (-1)^{|\sigma|} [\text{creation operators}] \cdot [\text{annihilation operators}] \\ &= (-1)^{|\sigma|} \hat{a}^\dagger \hat{b}^\dagger \dots \hat{u} \hat{v}, \end{aligned} \quad (2.32)$$

where \hat{P} is a permutation operator acting on the product of operators, and σ is the parity of the permutation. One should bear in mind that this definition is by no means unique. Here are some examples,

$$\begin{aligned} n[\hat{a}^\dagger \hat{b}] &= \hat{a}^\dagger \hat{b} & n[\hat{b} \hat{a}^\dagger] &= -\hat{a}^\dagger \hat{b} \\ n[\hat{a} \hat{b}] &= \hat{a} \hat{b} = -\hat{b} \hat{a} \\ n[\hat{a}^\dagger \hat{b}^\dagger] &= \hat{a}^\dagger \hat{b}^\dagger = -\hat{b}^\dagger \hat{a}^\dagger \\ n[\hat{a}^\dagger \hat{b} \hat{c}^\dagger \hat{d}] &= -\hat{a}^\dagger \hat{c}^\dagger \hat{b} \hat{d} = \hat{c}^\dagger \hat{a}^\dagger \hat{b} \hat{d} = \hat{a}^\dagger \hat{c}^\dagger \hat{d} \hat{b} = -\hat{c}^\dagger \hat{a}^\dagger \hat{d} \hat{b}. \end{aligned}$$

Note that the second quantised Hamiltonian in Equation 2.31 is already on normal-ordered form.

For two arbitrary creation and annihilation operators, we define their contraction as

$$\overline{\hat{A}\hat{B}} \equiv \langle - | \hat{A}\hat{B} | - \rangle, \quad (2.33)$$

equivalently,

$$\overline{\hat{A}\hat{B}} \equiv \hat{A}\hat{B} - n[\hat{A}\hat{B}]. \quad (2.34)$$

For a creation- and annihilation operator there are four possible contractions,

$$\begin{aligned} \overline{\hat{a}^\dagger \hat{b}^\dagger} &= \langle - | \hat{a}^\dagger \hat{b}^\dagger | - \rangle = \hat{a}^\dagger \hat{b}^\dagger - n[\hat{a}^\dagger \hat{b}^\dagger] = 0 \\ \overline{\hat{a} \hat{b}} &= \langle - | \hat{a} \hat{b} | - \rangle = \hat{a} \hat{b} - n[\hat{a} \hat{b}] = 0 \\ \overline{\hat{a}^\dagger \hat{b}} &= \langle - | \hat{a}^\dagger \hat{b} | - \rangle = \hat{a}^\dagger \hat{b} - n[\hat{a}^\dagger \hat{b}] = 0 \\ \overline{\hat{a} \hat{b}^\dagger} &= \langle - | \hat{a} \hat{b}^\dagger | - \rangle = \hat{a} \hat{b}^\dagger - n[\hat{a} \hat{b}^\dagger] = \hat{a} \hat{b}^\dagger - (-\hat{b}^\dagger \hat{a}) = \{\hat{a}, \hat{b}^\dagger\} = \delta_{ab}. \end{aligned} \quad (2.35)$$

We see that all contractions between creation- and annihilation operators are a number, most of them are zero and only those with a annihilation operator to the left and a creation operator to the right can be one.

Contractions inside a normal ordered product is defined as follows,

$$n[\hat{A}\hat{B}\hat{C}\dots\hat{R}\dots\hat{S}\dots\hat{T}\dots\hat{U}\dots] = (-1)^\sigma \overbrace{\hat{R}\hat{T}\hat{S}\hat{U}}^{\text{contraction}} \dots n[\hat{A}\hat{B}\hat{C}\dots], \quad (2.36)$$

where all contracted operator pairs are moved to the front of the normal ordered product, and σ is the parity of the permutations required for this relocation. The result will be zero, or plus or minus the normal ordered product without the contracted operator pairs.

2.4.2 Wick's Theorem

Wick's theorem states that every string of creation and annihilation operators can be written as a sum of normal-ordered products with all possible contractions,

$$\begin{aligned} \hat{A}\hat{B}\hat{C}\hat{D}\dots = & n[\hat{A}\hat{B}\hat{C}\hat{D}\dots] + n[\overbrace{\hat{A}\hat{B}}^{\text{contraction}}\hat{C}\hat{D}\dots] + n[\overbrace{\hat{A}\hat{C}}^{\text{contraction}}\hat{B}\hat{D}\dots] + n[\overbrace{\hat{A}\hat{D}}^{\text{contraction}}\hat{B}\hat{C}\dots] \\ & + \dots + n[\overbrace{\hat{B}\hat{C}}^{\text{contraction}}\hat{A}\hat{D}\dots] + n[\overbrace{\hat{B}\hat{D}}^{\text{contraction}}\hat{A}\hat{C}\dots] + \dots + n[\overbrace{\hat{C}\hat{D}}^{\text{contraction}}\hat{A}\hat{B}\dots] + \dots + \\ & + n[\overbrace{\hat{A}\hat{B}}^{\text{contraction}}\overbrace{\hat{C}\hat{D}}^{\text{contraction}}\dots] + n[\overbrace{\hat{A}\hat{C}}^{\text{contraction}}\overbrace{\hat{B}\hat{D}}^{\text{contraction}}\dots] + n[\overbrace{\hat{A}\hat{D}}^{\text{contraction}}\overbrace{\hat{B}\hat{C}}^{\text{contraction}}\dots] + \dots, \end{aligned} \quad (2.37)$$

where eventually all possible contractions of one, two pairs etc, are included.

Especially when computing vacuum expectation values of normal-ordered products is Wick's theorem very important. The reason for this is that each contraction will not contribute to the result, unless it is a fully contracted operator string,

$$\langle |\hat{A}\dots\hat{B}\dots\hat{C}\dots\hat{D}\dots| \rangle = \sum_{\text{all possible contractions}} \langle |n[\overbrace{\hat{A}\dots\hat{B}\dots\hat{C}\dots\hat{D}\dots}^{\text{contraction}}]| \rangle. \quad (2.38)$$

Most vacuum expectation values contain operators strings already have substrings that are already normal-ordered. This warrants a very useful generalisation of Wick's theorem for such strings,

$$\begin{aligned} n[\hat{A}_1\hat{A}_2\dots]n[\hat{B}_1\hat{B}_2\dots]\dots n[\hat{Z}_1\hat{Z}_2\dots] = & n[\hat{A}_1\hat{A}_2\dots:\hat{B}_1\hat{B}_2\dots:\dots:\hat{Z}_1\hat{Z}_2\dots] \\ & + \sum_{(1)} n[\overbrace{\hat{A}_1\hat{A}_2\dots}^{\text{contraction}}:\hat{B}_1\hat{B}_2\dots:\dots:\hat{Z}_1\hat{Z}_2\dots] + \dots + \sum_{(n)} n[\overbrace{\hat{A}_1\dots\hat{Z}_N}^{\text{contraction}}], \end{aligned} \quad (2.39)$$

where we sum over all combinations of contractions that each involve operators from different substrings, starting with one contractions and up to when all operators, or as many as possible, are contracted.

2.4.3 Particle-Hole Formalism

We see that a Slater determinant can be built recursively with creation operators,

$$\hat{I} = i_1 i_2 \dots i_N = \hat{i}_1^\dagger \hat{i}_2^\dagger \dots \hat{i}_N^\dagger | \rangle. \quad (2.40)$$

Instead of rewriting Slater determinants with operators applied to the vacuum state in this manner we will introduce the convenient reference state, or Fermi vacuum, Slater determinant,

$$|0\rangle = |\Phi_0\rangle = |ijk\dots n\rangle. \quad (2.41)$$

We will define other Slater determinants relative to this reference state. For instance,

$$|\Phi_i^a\rangle \equiv \hat{a}^\dagger \hat{i} |\Phi_0\rangle = |ajk \dots n\rangle \quad (2.42)$$

$$|\Phi_{ij}^{ab}\rangle \equiv \hat{a}^\dagger \hat{b}^\dagger \hat{j} \hat{i} |\Phi_0\rangle = |abk \dots n\rangle \quad (2.43)$$

$$|\Phi_i\rangle \equiv \hat{i} |\Phi_0\rangle = |jk \dots n\rangle \quad (2.44)$$

$$|\Phi^a\rangle \equiv \hat{a}^\dagger |\Phi_0\rangle = |aijk \dots n\rangle \quad (2.45)$$

where equations 2.42, 2.43 2.44 and 2.45 constitutes a single excitation, a double excitation, an electron removal and an electron attachment, respectively. Note that these reference relative Slater determinants have the following properties,

$$|\Phi_{ij}^{ab}\rangle = |\Phi_{ji}^{ba}\rangle = -|\Phi_{ij}^{ba}\rangle = -|\Phi_{ji}^{ab}\rangle. \quad (2.46)$$

Take note of the specific letters used for creating and annihilating electrons in the example above. i, j, k, l, \dots are letters restricted to indices of *hole* states, a, b, c, d, \dots are letters restricted to indices of *particle* states and the p, q, r, \dots are for general use, indicating any state. Notice that

$$\begin{aligned} \hat{i}^\dagger |0\rangle &= 0 & \hat{a} |0\rangle &= 0, \\ \langle 0 | \hat{i} &= 0 & \langle 0 | \hat{a}^\dagger &= 0. \end{aligned} \quad (2.47)$$

Whenever we try to insert an electron where there already is one, or when we try to remove an electron that is not there, we get zero as result.

2.4.4 Wick's theorem relative to the Fermi vacuum

Now we will modify the concepts of normal-ordering, contractions and Wick's theorem so that the work better in conjunction with the Fermi vacuum, instead of the physical vacuum.

First we introduce pseudo-operators,

$$\begin{aligned} \hat{b}_i &= \hat{i}^\dagger, & \hat{b}_i^\dagger &= \hat{i} \\ \hat{b}_a &= \hat{a}^\dagger, & \hat{b}_i^\dagger &= \hat{a}^\dagger, \end{aligned} \quad (2.48)$$

where \hat{b}_i^\dagger is a hole creation operator and \hat{b}_i is a particle creation operator, but only for vacant spaces below the fermi level. The reasoning for introducing such operators is to be able to work with the fermi vacuum in the same manner as regular operators work with the physical vacuum.

We introduce a new type of normal ordering for the pseudo-operators (and for the actual operators that they represent),

$$\{\hat{A}\hat{B}\hat{C}\} = (-1)^{\hat{b}_p^\dagger \hat{b}_q^\dagger \dots \hat{b}_u \hat{b}_v}. \quad (2.49)$$

We write a contraction in the same manner,

$$\overline{\hat{A}\hat{B}} = \hat{A}\hat{B} - \{\hat{A}\hat{B}\}. \quad (2.50)$$

A normal-ordered product with contractions inside is also defined the same way.

For contractions we see that the only non-zero contractions are

$$\overline{\hat{b}_i \hat{b}_j^\dagger} = \overline{\hat{i}^\dagger \hat{j}} = \delta_{ij}, \quad \overline{\hat{b}_a \hat{b}_b^\dagger} = \overline{\hat{a} \hat{b}^\dagger} = \delta_{ab}. \quad (2.51)$$

Here we are also made aware the first benefit of pseudo-operators. More generally we have the anticommutator relations

$$\{\hat{b}_p, \hat{b}_q^\dagger\} = \delta_{pq}, \quad \{\hat{b}_p, \hat{b}_q\} = 0 \quad (2.52)$$

Excited Slater determinants can be written using pseudo-operators,

$$|\Phi_i^a\rangle \equiv \hat{b}_a^\dagger \hat{b}_i^\dagger |\Phi_0\rangle \quad (2.53)$$

$$|\Phi_{ij}^{ab}\rangle \equiv \hat{b}_b^\dagger \hat{b}_j^\dagger \hat{b}_a^\dagger \hat{b}_i^\dagger |\Phi_0\rangle \quad (2.54)$$

Teil II

Quantum Many-Body Approximations

Kapitel 3

Hartree-Fock Theory

In 1927, soon after the discovery of the Schrödinger equation in 1926, Douglas R. Hartree introduced a procedure which he called the self-consistent field method[21]. Hartree sought to do without empirical parameters and to solve the many-body time-independent Schrödinger equation from fundamental principles, *ab initio*. A year later John C. Slater and John A. Gaunt provided a sounder theoretical basis for the Hartree method by applying the variational principle to a trial wave function as a product of single-particle functions[54][19]. Slater later pointed out, with support from Vladimir A. Fock, that the method merely applied the Pauli exclusion principle in its older, incorrect formulation; forbidding presence of two electrons in the same state, but neglecting quantum statistics[53][18]. It was shown that a Slater determinant satisfies the antisymmetric property of the exact solution and would be a suitable ansatz for applying the variational principle. Later, Hartree reformulated the method for calculation[22].

The Hartree-Fock methods makes the following simplifications to the multi-electron atomic (molecular) problem,

- The full molecular wavefunction is constrained to a function of the coordinates of only the electrons in the molecule. In not so many words, the Born-Oppernheimer approximation is inherent in the method.
- Any relativistic effects are completely ignored, i.e. the momentum operator is assumed to be completely non-relativistic.
- A variational solution is assumed to be a linear combination of a basis set, which is assumed to be approximately complete. This set of basis functions is usually orthogonal, but may not be.
- Some electron correlation effects are ignored, as the method implies a mean-field approximation. Coulomb correlation is fully incorporated in the Hartree-Fock method, but it ignores Fermi Correlation and is therefore unable to describe some effects, like London dispersion¹.
- Any energy eigenfunction is assumed to be describable by a single Slater determinant.

Relaxation of the last two simplifications give rise to the large group of many-body methods commonly referred to as post-Hartree-Fock methods.

¹Named after Fritz London; London dispersion forces (LDF) are a type of force between atoms and molecules[24]

3.1 Deriving the Hartree-Fock Equations

Consider a Hamiltonian for some system

$$\hat{H} = \hat{H}_0 + \hat{W}, \quad \hat{H}_0 = \sum_i^N \hat{h}(i), \quad (3.1)$$

where the ground state of \hat{H}_0 is a Slater determinant consisting of N single-particle functions,

$$\Phi = \mathcal{A} \phi_1 \phi_2 \dots \phi_N, \quad \langle \phi_i | \phi_j \rangle = \delta_{ij}. \quad (3.2)$$

If \hat{W} is only a limited perturbation to the system, it is reasonable to assume that the actual ground state of the full system can also be represented by a Slater determinant. Because the Hartree-Fock theory includes a mean-field approximation, each particle moves independently of the others interacting with the remaining electrons only indirectly through an average potential \hat{v}^{HF} .

The expectation value of the Hamiltonian in Equation 3.1 is

$$\langle \Phi | \hat{H} | \Phi \rangle = \sum_i \langle \phi_i | \hat{h} | \phi_i \rangle + \frac{1}{2} \sum_{ij} \langle \phi_i \phi_k | \hat{w} | \phi_i \phi_j - \phi_j \phi_i \rangle, \quad (3.3)$$

where

$$\langle \phi_i \phi_j | \hat{w} | \phi_k \phi_l \rangle = \int \int \bar{\phi}_i(1) \bar{\phi}_j(2) \hat{w}(1, 2) \phi_k(1) \phi_l(2) d1 d2$$

Now we want to minimise the energy (Equation 3.1) under the constraint of orthonormal single-particle functions, id est $\langle \phi_i | \phi_k \rangle = \delta_{ij}$. The minimum solution is called the Hartree-Fock state, $|\Phi_{\text{HF}}\rangle$. An optimisation problem with a constraint begs the formulation of a Lagrangian functional with a Lagrange multiplier for each constraint,

$$\begin{aligned} \mathcal{L}(\phi_1, \dots, \phi_n, \lambda) &= \langle \Phi | \hat{H} | \Phi \rangle - \sum_{ij} \lambda_{ij} (\langle \phi_i | \phi_j \rangle - \delta_{ij}) \\ &= \sum_i \langle \phi_i | \hat{h} | \phi_i \rangle + \frac{1}{2} \sum_{ij} \langle \phi_i \phi_j | \hat{w} | \phi_i \phi_j - \phi_j \phi_i \rangle - \sum_{ij} \lambda_{ij} (\langle \phi_i | \phi_j - \delta_{ij} \rangle). \end{aligned} \quad (3.4)$$

The constraints can always be treated separately, $\partial \mathcal{L} / \partial \lambda_{ij} \langle \phi_i | \phi_j \rangle - \delta_{ij}$, as this demand will be fulfilled by finding that the solutions ϕ_i are orthonormal.

In order to find the optimum of the Lagrangian in (Equation 3.4), we choose a $k \in \{1, \dots, N\}$ and compute the directional derivative of ϕ_k^* , by varying this single particle function and leaving all others fixed,

$$\delta \phi_k = \epsilon \eta, \quad \delta \phi_l = 0, k \neq l, \quad (3.5)$$

where ϵ is some small number, and η is a normalized single-particle function. We define a function representing this variation,

$$f(\epsilon) = \mathcal{L}(\phi_1, \dots, \phi_k + \epsilon \eta, \dots, \phi_N, \lambda), \quad (3.6)$$

expanded to first order in ϵ ,

$$f(\epsilon) = f(0) + \epsilon f'(0) + \mathcal{O}(\epsilon^2). \quad (3.7)$$

For an optimum we must have

$$f'(0) = 0, \quad \forall \eta, \quad (3.8)$$

which means that the directional derivative of \mathcal{L} at $\{\phi_i\}_{i=1}^N$, in the direction η vanishes.

We compute the Taylor expansion of the varied Lagrangian (Equation 3.6),

$$f(\epsilon) = \sum_i \langle \phi_i + \delta_{ki}\epsilon\eta | \hat{h} | \phi_i \rangle + \frac{1}{2} \sum_{ij} \langle (\phi_i + \delta_{ki}\epsilon\eta)(\phi_j + \delta_{kj}\epsilon\eta) | \hat{w} | \phi_i\phi_j - \phi_j\phi_i \rangle - \sum_{ij} \lambda_{ij} (\langle \phi_i + \delta_{ik}\epsilon\eta | \phi_j \rangle - \delta_{ij}) + \mathcal{O}(\epsilon^2) \quad (3.9)$$

$$= \sum_i \langle \phi_i | \hat{h} | \phi_i \rangle + \frac{1}{2} \sum_i j \langle \phi_i\phi_j | \hat{w} | \phi_i\phi_j - \phi_j\phi_i \rangle + \epsilon \langle \eta | \hat{h} | \phi_k \rangle + \frac{1}{2} \sum_{ij} \langle \phi_i\delta_{kj}\epsilon\eta | \hat{w} | \phi_i\phi_j - \phi_j\phi_i \rangle + \frac{1}{2} \sum_{ij} \langle \delta_{ki}\epsilon\eta\phi_j | \hat{w} | \phi_i\phi_j - \phi_j\phi_i \rangle - \sum_{ij} \lambda_{ij} (\langle \phi_i | \phi_j \rangle - \delta_{ij}) - \sum_{ij} \lambda_{ij} (\langle \delta_{ik}\epsilon\eta | \phi_j \rangle - \delta_{ij}) + \mathcal{O}(\epsilon^2) \quad (3.10)$$

$$= \sum_i \langle \phi_i | \hat{h} | \phi_i \rangle + \frac{1}{2} \sum_i j \langle \phi_i\phi_j | \hat{w} | \phi_i\phi_j - \phi_j\phi_i \rangle + \epsilon \langle \eta | \hat{h} | \phi_k \rangle - \sum_{ij} \lambda_{ij} (\langle \phi_i | \phi_j \rangle - \delta_{ij}) + \frac{1}{2} \epsilon \sum_i \langle \phi_i\eta | \hat{w} | \phi_i\phi_k \rangle - \frac{1}{2} \epsilon \sum_i \langle \phi_i\eta | \hat{w} | \phi_k\phi_i \rangle + \frac{1}{2} \epsilon \sum_j \langle \eta\phi_j | \hat{w} | \phi_k\phi_j \rangle - \frac{1}{2} \epsilon \sum_j \langle \eta\phi_j | \hat{w} | \phi_j\phi_k \rangle - \epsilon \sum_j \lambda_{jk} \langle \eta | \phi_j \rangle + \mathcal{O}(\epsilon^2) \quad (3.11)$$

$$= \sum_i \langle \phi_i | \hat{h} | \phi_i \rangle + \frac{1}{2} \sum_i j \langle \phi_i\phi_j | \hat{w} | \phi_i\phi_j - \phi_j\phi_i \rangle - \sum_{ij} \lambda_{ij} (\langle \phi_i | \phi_j \rangle - \delta_{ij}) + \epsilon \langle \eta | \hat{h} | \phi_k \rangle + \epsilon \sum_i \langle \eta\phi_i | \hat{w} | \phi_k\phi_i \rangle - \epsilon \sum_i \langle \eta\phi_i | \hat{w} | \phi_i\phi_k \rangle - \epsilon \sum_j \lambda_{jk} \langle \eta | \phi_j \rangle + \mathcal{O}(\epsilon^2) \quad (3.12)$$

Notice that the zeroth term, represented by the first line in Equation 3.12, is simply the original Lagrangian in Equation 3.4. We equate all the first-order terms to zero,

$$\langle \eta | \hat{h} | \phi_k \rangle + \sum_i \langle \eta\phi_i | \hat{w} | \phi_k\phi_i \rangle - \sum_i \langle \eta\phi_i | \hat{w} | \phi_i\phi_k \rangle - \sum_i \lambda_{ik} \langle \eta | \phi_i \rangle = 0. \quad (3.13)$$

This must be valid for any choice η , meaning

$$\hat{h} | \phi_k \rangle + \sum_i \langle \cdot | \phi_i | \hat{w} | \phi_k\phi_i \rangle - \sum_i \langle \cdot | \phi_i | \hat{w} | \phi_i\phi_k \rangle - \sum_i \lambda_{ik} | \phi_i \rangle = 0, \quad (3.14)$$

where $\langle \cdot | \phi_1 | \hat{w} | \phi_2\phi_3 \rangle \in L_1^2$ is interpreted as an integral over only the second particle in the matrix element. We define,

$$\hat{v}_{\text{HF}} = \hat{v}_{\text{direct}} + \hat{v}_{\text{exchange}} = \sum_i \langle \cdot | \phi_i | \hat{w} | \phi_k\phi_i \rangle - \sum_i \langle \cdot | \phi_i | \hat{w} | \phi_i\phi_k \rangle \quad (3.15)$$

$$\hat{f} = \hat{h} + \hat{v}_{\text{HF}}, \quad (3.16)$$

and can then rewrite Equation 3.14 to

$$\hat{f}|\phi_i\rangle = \sum_j \lambda_{ij} |\phi_j\rangle, \quad (3.17)$$

which are the non-canonical Hartree-Fock equations.

It so happens that the Slater determinant $|\Phi\rangle$ is invariant under unitary transformation of the single particle functions. Consider

$$\tilde{\phi}_k = \sum_j \phi_j U_{jk}, \quad (3.18)$$

where U is a unitary matrix. This implies that $|\tilde{\Phi}\rangle = \det(U)|\Phi\rangle$, is the same state and the energy must be the same as well. We choose a particular unitary transformation U , rotating the single particle functions in a certain manner so that $\lambda = UEU^H$, where $E_{jk} = \delta_{jk}\epsilon_k$ are the elements of a diagonal matrix (the eigenvalues of λ). This provides us with a new set of eigenvalue equations,

$$\hat{f}(\tilde{\phi}_1, \dots, \tilde{\phi}_N) |\tilde{\phi}_i\rangle = \epsilon_i |\tilde{\phi}_i\rangle, \quad (3.19)$$

which are the canonical Hartree-Fock equations. From now on we will stick with these equations and suppress the tilde notations.

3.2 The Roothan-Hall Equations

In order to solve the Hartree-Fock equations (Equation 3.19) we render the equations in a finite, fixed basis $\{\chi_p\}_{p=1}^L$ of a finite size L . It is not a necessity for this basis to be orthonormal, and we therefore define the overlap matrix,

$$S_{pq} \equiv \langle \chi_p | \chi_q \rangle. \quad (3.20)$$

The Hartree-Fock single-particle functions are expanded in this basis,

$$|\phi_p\rangle = \sum_q |\chi_q\rangle U_{qp}, \quad (3.21)$$

where U is not necessarily unitary, because the basis is not necessarily orthogonal. However, we do have $U^H S U = \hat{1}$.

We insert the expansion from Equation 3.21 into the expression for the canonical Hartree-Fock equations from Equation 3.19,

$$\hat{f} \sum_r |\chi_r\rangle U_{rp} = \epsilon_p \sum_r |\chi_r\rangle U_{rp}. \quad (3.22)$$

Then we left project with an arbitrary function from our new basis,

$$\begin{aligned} \langle \chi_q | \hat{f} \sum_r |\chi_r\rangle U_{rp} &= \epsilon_p \langle \chi_q | \chi_r \rangle \sum_r U_{rp} \quad \forall q, p \\ \sum_r F_{qr} U_{rp} &= \epsilon_p \sum_r S_{qr} U_{rp} \quad \forall q, p \\ F(D)U &= SU\epsilon. \end{aligned} \quad (3.23)$$

where the last line is the Roothan-Hall equations.

Elaborating on the computation of the Fock matrix element,

$$F_{qp} = \langle \chi_q | \hat{f} | \chi_p \rangle = \langle \chi_q | \hat{h} | \chi_p \rangle + \langle \chi_q | \hat{v}_{\text{direct}} | \chi_p \rangle - \langle \chi_q | \hat{v}_{\text{exchange}} | \chi_p \rangle, \quad (3.24)$$

where

$$\begin{aligned} \langle \chi_q | \hat{v}_{\text{direct}} | \chi_p \rangle &= \sum_j \langle \chi_q \phi_j | \hat{w} | \chi_p \phi_j \rangle = \sum_{p'q'j} U_{jq'} U_{jp'}^* \langle \chi_q \chi_{q'} | \hat{w} | \chi_p \chi_{p'} \rangle \\ &= \sum_{p'q'} D_{p'q'} \langle \chi_q \chi_{q'} | \hat{w} | \chi_p \chi_{p'} \rangle \end{aligned} \quad (3.25)$$

$$\begin{aligned} \langle \chi_q | \hat{v}_{\text{exchange}} | \chi_p \rangle &= \sum_j \langle \chi_q \phi_j | \hat{w} | \phi_j \chi_p \rangle = \sum_{p'q'j} U_{jq'} U_{jp'}^* \langle \chi_q \chi_{q'} | \hat{w} | \chi_{p'} \chi_p \rangle \\ &= \sum_{p'q'} D_{p'q'} \langle \chi_q \chi_{q'} | \hat{w} | \chi_{p'} \chi_p \rangle, \end{aligned} \quad (3.26)$$

giving us,

$$F_{qp} = \langle \chi_q | \hat{h} | \chi_p \rangle + \sum_{p'q'} D_{p'q'} (\langle \chi_q \chi_{q'} | \hat{w} | \chi_p \chi_{p'} \rangle - \langle \chi_q \chi_{q'} | \hat{w} | \chi_{p'} \chi_p \rangle), \quad (3.27)$$

where $D = UU^H$, is the density matrix.

The benefit of the Roothan-Hall equations (Equation 3.21), is that they are represented by matrices, and therefore easy to implement on a computer. The Roothan-Hall equations are solved iterably, starting from an initial guess for U . This guess can be used to compute the density matrix, $D^{(k)} = \sum_i u_i^{(k)} (u_i^{(k)})^*$, where k denotes the iteration. The density matrix is used to compute the Fock matrix. This provides us with a general eigenvalue problem, from which a new U and ϵ can be found. This formula is then repeated until the iterations converge. At this point we say that we have self-consistency in the mean field, and this method is usually called the method of self-consistent field (SCF) iterations.

3.3 Restricted Hartree-Fock Theory

Consider some jolly band of N electrons confined in a potential. To begin with we will assume that these are non-interacting, and can therefore be described only by the one-body part of the Hamiltonian,

$$\hat{h}(\mathbf{r}) = \hat{t}(\mathbf{r}) + \hat{v}(\mathbf{r}), \quad (3.28)$$

where \hat{v} is potential set up by an atomic nucleus, or some other confining force. The one-body operators \hat{h} does not couple to electron spin, so the spinorbitals or single-particle eigenfunctions of \hat{h} separate,

$$\phi_P(\mathbf{r}, \sigma) = \varphi_P(\mathbf{r}) \chi_\alpha(\sigma), \quad (3.29)$$

where $P = (p, \sigma)$ is the combined spin- and spatial index, $\alpha = \pm 1/2$ is the value of the projection of the electron spin along the z -axis. The spin index/coordinate can only take values $\sigma = \pm 1$, and we have orthonormal spinorbitals, $\langle \chi_\alpha | \chi_\beta \rangle = \delta_{\alpha\beta}$.

We restrict the orbitals to have the same spatial wavefunction for spin up and spin down, and we consider only closed-shell configurations. This means that our molecular wavefunctions, in the form of a Slater determinant, can only have an even number of N electrons, with all electrons paired in such a manner that there are two spin values for each of the $n = N/2$ spatial orbitals. The N -electron ground state of \hat{h} is given by the first N eigenfunctions $\phi_{(p,\sigma)}$ occupied,

$$|\Phi\rangle = \left| \phi_{1,+} \phi_{1,-} \dots \phi_{\frac{N}{2},+} \phi_{\frac{N}{2},-} \right\rangle, \quad (3.30)$$

commonly also written as

$$|\Phi\rangle_{\text{RHF}} = |\varphi_1 \bar{\varphi}_1 \dots \varphi_{N/2} \bar{\varphi}_{N/2}\rangle. \quad (3.31)$$

The reasoning behind this restriction is that one would assume, for many systems, that the exact wavefunction has the same kind of structure. This is true for almost all electronic systems in nature. We therefore do not optimise all the N single-particle functions freely, but assume that they form sets of doubly occupied spatial orbitals. Matrix elements can now be computed more easily on the restricted form,

$$\langle \phi_{(p,\alpha)} | \hat{h} | \phi_{(q,\beta)} \rangle = \langle \chi_\alpha | \chi_\beta \rangle \int d\mathbf{r} \varphi_p(\mathbf{r})^* \hat{h} \varphi_q(\mathbf{r}). \quad (3.32)$$

And similarly for two-body operators,

$$\langle \phi_{p\alpha} \phi_{q\beta} | \hat{w} | \phi_{r\gamma} \phi_{s\delta} \rangle = \langle \chi_\alpha | \chi_\gamma \rangle \langle \chi_\beta | \chi_\delta \rangle \int \int d\mathbf{r}_1 d\mathbf{r}_2 \varphi_p(\mathbf{r}_1) \varphi_q(\mathbf{r}_2) \hat{w}(\mathbf{r}_1 \mathbf{r}_2) \varphi_r(\mathbf{r}_1) \varphi_s(\mathbf{r}_2) \quad (3.33)$$

Now we will find the special form of the Fock operator in restricted Hartree-Fock theory. First we insert the wavefunction restriction into the Hartree-Fock equation

$$\begin{aligned} \hat{f} \phi_I(\mathbf{r}, \sigma) &= \epsilon_i \phi_I(\mathbf{r}, \sigma) \\ \hat{f} \varphi(\mathbf{r}) \chi_\alpha(\sigma) &= \epsilon_i \varphi(\mathbf{r}) \chi_\alpha(\sigma). \end{aligned} \quad (3.34)$$

Here we have joined the spatial- and spin index with a capital letter $I = (i, \alpha)$. We left multiply with χ_α^* , suppress indices for brevity and integrate over spin,

$$\langle \chi_\alpha | \hat{f} | \varphi_i \chi_\alpha \rangle = \langle \chi_\alpha | \hat{f} | \phi_{I=(i,\alpha)} \rangle = \epsilon_i \varphi_i. \quad (3.35)$$

Next we insert the Fock operator,

$$\hat{f} = \hat{h} + \sum_i \langle \cdot \varphi_i | (\hat{w} - \hat{P}_{12}) | \cdot \varphi_i \rangle$$

This special notation means that we integrate over the second orbital in the bra and ket only. After insertion we get

$$\begin{aligned} \langle \chi_\alpha | \hat{h} | \chi_\alpha \rangle \varphi_i + \sum_J \langle \chi_\alpha \phi_J | (\hat{w} - \hat{P}_{12}) | \phi_I \phi_J \rangle &= \epsilon_i \varphi_i \\ \rightarrow \hat{h} \varphi_i + \sum_J \langle \chi_\alpha \phi_J | \hat{w} | \phi_I \phi_J \rangle - \sum_J \langle \chi_\alpha \phi_J | \hat{w} | \phi_J \phi_I \rangle &= \epsilon_i \varphi_i. \end{aligned} \quad (3.36)$$

Because if we have a closed-shell system, then over occupied spinorbitals include an equal sum over spin up and spin down functions so that

$$\sum_J^n = \sum_\beta \sum_j^{n/2}.$$

We next insert this into our eigenvalue equation and split the single-particle functions into separate spin- and spatial orbitals,

$$\begin{aligned} \hat{h} \varphi_i + \sum_\beta \sum_j^{n/2} \langle \chi_\alpha \varphi_j \chi_\beta | \hat{w} | \varphi_i \chi_\alpha \varphi_j \chi_\beta \rangle - \sum_\beta \sum_j^{n/2} \langle \chi_\alpha \varphi_j \chi_\beta | \hat{w} | \varphi_j \chi_\beta \varphi_i \chi_\alpha \rangle \\ = \hat{h} \varphi_i + 2 \sum_j^{n/2} \langle \cdot \varphi_j | \hat{w} | \varphi_i \varphi_j \rangle + \sum_j^{n/2} \langle \cdot \varphi_j | \hat{w} | \varphi_j \varphi_i \rangle = \epsilon_i \varphi_i. \end{aligned} \quad (3.37)$$

We now have the form of the Fock operator within the restricted Hartree-Fock theory,

$$\begin{aligned}\hat{f} &= \hat{h} + \sum_i^{n/2} \langle \cdot | \varphi_i | (2\hat{w} - \hat{P}_{12}) | \cdot | \varphi_i \rangle \\ &= \hat{h} + 2 \sum_i^{n/2} \int d\mathbf{r}_2 \varphi_i^*(\mathbf{r}_2) \hat{w} \varphi_i(\mathbf{r}_2) - \sum_i^{n/2} \int d\mathbf{r}_2 \varphi_i^*(\mathbf{r}_2) \hat{w} \varphi_j(\mathbf{r}_2)\end{aligned}\quad (3.38)$$

The Hartree-Fock energy also has a special form in the restricted Hartree-Fock realm,

$$\begin{aligned}\langle \Phi | \hat{H} | \Phi \rangle &= \sum_P \langle \phi_P | \hat{h} | \phi_P \rangle + \frac{1}{2} \sum_P \sum_Q \langle \phi_P \phi_Q | (\hat{w} - \hat{P}_{12}) | \phi_P \phi_Q \rangle \\ &= \sum_\alpha \sum_p^{n/2} \langle \phi_{(p,\alpha)} | \hat{h} | \phi_{(p,\alpha)} \rangle \\ &\quad + \sum_\alpha \sum_p^{n/2} \sum_\beta \sum_q^{n/2} \langle \phi_{(p,\alpha)} \phi_{(q,\beta)} | \hat{w} (|\phi_{(p,\alpha)} \phi_{(q,\beta)}\rangle - |\phi_{(q,\beta)} \phi_{(p,\alpha)}\rangle) \\ &= 2 \sum_p^{n/2} \langle \varphi_p | \hat{h} | \varphi_p \rangle + 2 \sum_{pq}^{n/2} \langle \varphi_p \varphi_q | \hat{w} | \varphi_p \varphi_q \rangle - \sum_{pq}^{n/2} \langle \varphi_p \varphi_q | \hat{w} | \varphi_p \varphi_q \rangle\end{aligned}\quad (3.39)$$

3.4 Unrestricted Hartree-Fock Theory

The restricted Hartree-Fock model is often a good enough approximation, but under some circumstances it will fail to provide a good result. The unrestricted Hartree-Fock model is an intermediate between the general Hartree-Fock model and the restricted Hartree-Fock model. Compared with the restricted Hartree-Fock single-particle wavefunction form, the unrestricted form is somewhat obvious as we now allow the spins to be different,

$$\phi_P(\mathbf{r}, \sigma) = \varphi_p^\alpha(\mathbf{r}) \chi_\alpha(\sigma), \quad (3.40)$$

where we have given the spatial orbitals a spin-index as well. As before, a capital index is the combined spatial- and spin index $P = (p, \alpha)$, where $P \in [1, L]$, $p \in [1, L/2]$ and $\alpha = \pm 1/2$. Like before, we require the states to be orthonormal

$$\langle \phi_P | \phi_Q \rangle = \langle \varphi_p^\alpha | \varphi_q^\beta \rangle \varphi_\alpha \chi_\alpha \varphi_\beta = \delta_{PQ}. \quad (3.41)$$

we can write a general unrestricted Hartree-Fock state as

$$|\Phi\rangle_{\text{UHF}} = |\varphi_1^{1/2} \varphi_1^{-1/2} \varphi_2^{1/2} \varphi_2^{-1/2} \dots \varphi_{L/2}^{1/2} \varphi_{L/2}^{-1/2}\rangle = |\phi_1 \phi_2 \phi_3 \phi_4 \dots \phi_{L-1} \phi_L\rangle. \quad (3.42)$$

In order to find an expression for the Fock operator we insert the wavefunction into the canonical Hartree-Fock equation,

$$\hat{f} \phi_P = \epsilon_P \phi_P, \rightarrow \hat{f} \varphi_p^\alpha \chi_\alpha = \epsilon_P \varphi_p^\alpha \chi_\alpha. \quad (3.43)$$

Now we left multiply by χ_α^* and integrate over spin,

$$\langle \chi_\alpha | \hat{f} | \varphi_p^\alpha \chi_\alpha \rangle = \langle \chi_\alpha | \epsilon_P | \varphi_p^\alpha \chi_\alpha \rangle \quad (3.44)$$

$$\hat{f} \varphi_p^\alpha = \left[\int d\sigma_1 \chi_\alpha(\sigma_1)^* \hat{f}(\mathbf{r}, \sigma_1) \chi_\alpha(\sigma_1) \right] \varphi_p^\alpha = \epsilon_P \varphi_p^\alpha. \quad (3.45)$$

We now have what is called the spatial unrestricted Hartree-Fock equations. Inserting for the canonical Fock operator yields the following left-hand side

$$\begin{aligned}
\hat{f}^\alpha \varphi_p^\alpha &= \hat{h} \varphi_p^\alpha + \sum_Q^L \langle \chi_\alpha \phi_Q | \hat{w} | \varphi_p^\alpha \chi_\alpha \phi_Q \rangle q - \sum_Q^L \langle \chi_\alpha \phi_Q | \hat{w} | \phi_Q \varphi_p^\alpha \chi_\alpha \rangle \\
&= \hat{h} \varphi_p^\alpha + \sum_\beta \sum_q^{L/2} \langle \chi_\alpha \varphi_q^\beta \chi_\beta | \hat{w} | \varphi_p^\alpha \chi_\alpha \varphi_q^\beta \chi_\beta \rangle \\
&\quad - \sum_\beta \sum_q^{L/2} \langle \chi_\alpha \varphi_q^\beta \chi_\beta | \hat{w} | \varphi_q^\beta \chi_\beta \varphi_p^\alpha \chi_\alpha \rangle \\
&= \hat{h} \varphi_p^\alpha + \sum_\beta \sum_q^{L/2} \langle \cdot \varphi_q^\beta | \hat{w} | \cdot \varphi_q^\beta \rangle \varphi_p^\alpha - \sum_q^{L/2} \langle \cdot \varphi_q^\alpha | \hat{w} | \cdot \varphi_p^\alpha \rangle \varphi_q^\beta
\end{aligned} \tag{3.46}$$

This means that we get the following form for the spatial Fock operators in unrestricted Hartree-Fock

$$\hat{f}^\uparrow = \hat{h} + \sum_p^{L/2} [\hat{v}_{\text{Coulomb}}^\uparrow - \hat{v}_{\text{exchange}}^\uparrow] + \sum_p^{L/2} \hat{v}_{\text{Coulomb}}^\downarrow \tag{3.47}$$

$$\hat{f}^\downarrow = \hat{h} + \sum_p^{L/2} [\hat{v}_{\text{Coulomb}}^\downarrow - \hat{v}_{\text{exchange}}^\downarrow] + \sum_p^{L/2} \hat{v}_{\text{Coulomb}}^\uparrow \tag{3.48}$$

From the definition of the two spatial Fock operators in Equation 3.47 and Equation 3.48, we see that the two integro-differential eigenvalue equations that arises from inserting \hat{f}^\uparrow and \hat{f}^\downarrow into the canonical Hartree-Fock equation,

$$\hat{f}^\uparrow \varphi_p^\uparrow = \epsilon_p^\uparrow \varphi_p^\uparrow \tag{3.49}$$

$$\hat{f}^\downarrow \varphi_p^\downarrow = \epsilon_p^\downarrow \varphi_p^\downarrow, \tag{3.50}$$

are coupled and cannot be solved independently. The spin-up orbitals depend on the occupied spin-down orbitals and vice versa. This means that the two equations must be solved by a simultaneous iterative process.

We can also derive an equation for the unrestricted Hartree-Fock energy,

$$\begin{aligned}
E_{UHF} &= \langle \Phi_{\text{UHF}} | \hat{H} | \Phi_{\text{UHF}} \rangle \\
&= \sum_\alpha \sum_p^{L/2} \langle \varphi_p^\alpha \chi_\alpha | \hat{h} | \varphi_p^\alpha \chi_\alpha \rangle + \sum_\alpha \sum_p^{L/2} \sum_\beta \sum_q^{L/2} \langle \varphi_p^\alpha \chi_\alpha \varphi_q^\beta \chi_\beta | (\hat{w} - \hat{P}_{12}) | \varphi_p^\alpha \chi_\alpha \varphi_q^\beta \chi_\beta \rangle \\
&= \sum_\alpha \sum_{pq}^{L/2} \langle \varphi_p^\alpha | \hat{h} | \varphi_p^\alpha \rangle + \sum_{\alpha\beta} \sum_q^{L/2} \langle \varphi_p^\alpha \varphi_q^\beta | \hat{w} | \varphi_p^\alpha \varphi_q^\beta \rangle - \sum_\alpha \sum_{pq}^{L/2} \langle \varphi_p^\alpha \varphi_q^\alpha | \hat{w} | \varphi_q^\alpha \varphi_p^\alpha \rangle
\end{aligned} \tag{3.51}$$

3.4.1 Pople-Nesbet-Bethier...

... would be nice to have here.

3.5 Time-Dependent Hartree-Fock

This section follows closely the narrative of the gentlemen Hochstuhl, Hinz and Bonitz[31]. Deriving the time-dependent Hartree-Fock equations start, of course, with the time-dependent Schrödinger equation,

$$i\hbar \frac{\partial}{\partial t} |\Phi(t)\rangle = \hat{H}(t) |\Phi(t)\rangle, \quad (3.52)$$

where the Hamiltonian is

$$\hat{H}(t) = \hat{h}(t) + \hat{w}(t). \quad (3.53)$$

This is very similar to the one used the same, except for the introduction of a time-dependence. We start by multiplying from the left with the reference Slater determinant $\langle \Phi |$. The right-hand side of the Schrödinger equation becomes the familiar Hartree-Fock energy,

$$\langle \Phi | \hat{H} | \Phi \rangle = \sum_p \langle \phi_p | \hat{h} | \phi_p \rangle + \frac{1}{2} \sum_{pq} \langle \phi_p \phi_q | (\hat{w} + \hat{P}_{12}) | \phi_p \phi_q \rangle. \quad (3.54)$$

The left-hand side, is more interesting,

$$\langle \Phi | \frac{\partial}{\partial t} | \Phi \rangle = \sum_p \langle \phi_p | \frac{\partial}{\partial t} | \phi_p \rangle, \quad (3.55)$$

which we will deal with in due time, but before doing so we need to introduce functional derivatives and the functional derivatives of various matrix elements. First, the one-body matrix elements,

$$\frac{\delta}{\delta \phi_r^*} \sum_p \langle \phi_p | \hat{h} | \phi_p \rangle = \sum_p \frac{\delta}{\delta \phi_r^*} \int dr \phi_p^* \hat{h} \phi_p = \sum_p \delta_{pr} \hat{h} = \hat{h} | \phi_r \rangle. \quad (3.56)$$

Second, the matrix elements of the time-derivate,

$$\frac{\delta}{\delta \phi_r^*} \sum_p \langle \phi_p | \frac{\partial}{\partial t} | \phi_p \rangle = \frac{\partial}{\partial t} | \phi_q \rangle, \quad (3.57)$$

which is so similar to the one-body computation that the result is simply written down, instead of computing the result explicitly. Lastly, we have the two-body matrix elements,

$$\begin{aligned} \frac{\delta}{\delta \phi_r^*} \sum_{pq} \langle \phi_p \phi_q | (\hat{w} - \hat{P}_{12}) | \phi_p \phi_q \rangle \\ = \frac{\delta}{\delta \phi_r^*(r_1)} \sum_{pq} \int dr_1 dr_2 \phi_p^*(r_1) \phi_q^*(r_2) (\hat{w} - \hat{P}_{12}) \phi_p(r_1) \phi_q(r_2) \\ = \sum_{pq} \delta_{pq} \int dr_2 \phi_q^*(r_2) (\hat{w} - \hat{P}_{12}) \phi_p(r_1) \phi_q(r_2) = \sum_q \langle \cdot \phi_q | (\hat{w} - \hat{P}_{12}) | \phi_r \phi_q \rangle. \end{aligned} \quad (3.58)$$

Now we want to vary the reference state to find the optimal one, applying the so-called time-dependent variational principle,

$$\langle \delta \Phi | (\hat{H} - i\hbar \frac{\partial}{\partial t}) | \Phi \rangle = 0, \quad (3.59)$$

which we want to minimise under the requirement of orthonormal single-particle functions in time,

$$\langle \phi_p(t) | \phi_q(t) \rangle = \delta_{pq}. \quad (3.60)$$

Such an optimization problem under a constraint begs for the formulation of a Lagrangian, which we will let manifest itself,

$$\mathcal{L}(\Phi, \lambda_{pq}) = \langle \Phi | (\hat{H} - i\hbar \frac{\partial}{\partial t}) | \Phi \rangle - \sum_{pq} \lambda_{pq} (\langle \phi_p | \phi_q \rangle - \delta_{pq}). \quad (3.61)$$

We find a stationary point of this Lagrangian functional, by variation of the single-particle functions so that

$$\frac{\delta \mathcal{L}}{\delta \phi_r^*} = 0, \quad \forall r. \quad (3.62)$$

This is where we will make use of the functional derivatives we computed before,

$$\frac{\delta \mathcal{L}}{\delta \phi_r^*} = \hat{h} |\phi_r\rangle + \sum_q \langle \phi_q | (\hat{w} - \hat{P}_{12}) | \phi_r \phi_q \rangle - i\hbar \frac{\partial}{\partial t} |\phi_r\rangle - \sum_q \lambda_{rq} |\phi_r\rangle = 0. \quad (3.63)$$

Now we want to solve for the Lagrange multiplier, we do this by left-projection of the functional derivative above with $\langle \phi_s |$ and move resulting multiplier λ_{sq} to the left, and all other terms to the right. We get the following expression for the Lagrange multiplier,

$$\lambda_{sq} = \langle \phi_s | \hat{h} | \phi_r \rangle + \langle \phi_s \phi_q | (\hat{w} - \hat{P}_{12}) | \phi_r \phi_q \rangle - i\hbar \langle \phi_s | \frac{\partial}{\partial t} | \phi_r \rangle \quad (3.64)$$

We insert this expression for the Lagrange multiplier into Equation 3.63 which results in,

$$\hat{P} \left[\hat{h} |\phi_r\rangle + \sum_q \langle \phi_q | (\hat{w}, \hat{P}_{12}) | \phi_r \phi_q \rangle - i\hbar \frac{\partial}{\partial t} |\phi_r\rangle \right] = 0, \quad (3.65)$$

where we have the confusing operator \hat{P} , which is not a permutation operator like \hat{P}_{12} , but a projection operator;

$$\hat{P} = \hat{1} - \sum_p |\phi_p\rangle \langle \phi_p|. \quad (3.66)$$

Rearranging Equation 3.65 yields

$$i\hbar \hat{P} \frac{\partial}{\partial t} |\phi_r\rangle = \hat{P} \left[\hat{h} |\phi_r\rangle + \langle \phi_q | (\hat{w} - \hat{P}_{12}) | \phi_r \phi_q \rangle \right] |\phi_r\rangle = \hat{P} \hat{f} |\phi_r\rangle, \quad (3.67)$$

where we see that Fock operator has appeared. This equation is an integro-differential equation, as the projection operator \hat{P} appear on both sides of the equality sign, and a solution can be difficult to find. Because the time-dependent Hartree-Fock wavefunction is invariant under unitary transformation, we can obtain equations that are numerically more appropriate, by applying a unitary transformation $\hat{Q}(t)$ which satisfies

$$i\hbar \langle \phi_p | \frac{\partial}{\partial t} | \phi_q \rangle \equiv \langle \phi_p | \hat{Q}(t) | \phi_q \rangle. \quad (3.68)$$

It turns out that a reasonable choice for $\hat{Q}(t)$ is $\hat{f}t$, in which case Equation 3.67 becomes

$$i\hbar \frac{\partial}{\partial t} |\phi_p(t)\rangle = \hat{f}(t) |\phi_p(t)\rangle, \quad (3.69)$$

where we have explicitly written out the time-dependence. This is the time-dependent Hartree-Fock equation.

Now we pick a specific, finite and static basis $\{\chi_p\}_{p=1}^L$ and expand the Hartree-Fock single-particle functions in this basis,

$$|\phi_p\rangle(t) = \sum_q |\chi_q\rangle U_{qp}(t). \quad (3.70)$$

Notice that the basis set is indeed static, with no time-dependence, only the coefficients of the expansions $U_{pq}(t)$ evolve in time. We insert the expansion into Equation 3.69,

$$i\hbar \frac{\partial}{\partial t} \sum_q |\chi_q\rangle U_{pq}(t) = \hat{f}(t) \sum_q |\chi_q\rangle U_{pq}(t). \quad (3.71)$$

We left-project this equation with $\langle\chi_r|$,

$$\begin{aligned} i\hbar \frac{\partial}{\partial t} \sum_q U_{pq}(t) \langle\chi_r|\chi_q\rangle &= \sum_q U_{pq}(t) \langle\chi_r|\hat{f}(t)|\chi_q\rangle \\ &\rightarrow i\hbar \sum_q \dot{U}_{pq} S_{rq} = \sum_q U_{pq} \hat{f}_{rq}(t), \end{aligned} \quad (3.72)$$

which can be written as a matrix equation,

$$i\hbar \mathbf{S}\dot{\mathbf{U}}(t) = \mathbf{F}(t)\mathbf{U}(t). \quad (3.73)$$

Kapitel 4

Perturbation Theory

Perturbation theory is a very powerful method and a generic method applicable to all matrix problems. Additionally, perturbation theory is relatively cheap in terms of computing time especially compared with coupled cluster theory. As the method provides a different route to the solution of the Schrödinger equation, by approaching the exact solution systematically, based on an order-by-order expansion of the energy and wave function. Therefore, perturbation theory is often used to improve the results from other computation schemes. What is more, the exponential form of the wave function in coupled cluster theory stems from the non-degenerate Rayleigh-Schrödinger perturbation theory (RSPT) expansion.

4.1 Formal perturbation theory

We split the Hamiltonian into a known part and a perturbed part,

$$\hat{H} = \hat{H}_0 + \hat{V}. \quad (4.1)$$

Sometimes it is convenient to write

$$\hat{H} = \hat{H}_0 + \lambda \hat{V}, \quad (4.2)$$

where we have included an order parameter λ . This parameter is used to categorise the contributions of different order. The exact solution is given by

$$\begin{aligned} \hat{H}\Psi_n &= E_n\Psi_n \\ (\hat{H}_0 + \hat{V})\Psi_n &= E_n\Psi_n, \quad \Psi_n = \Phi_n + \chi_n \end{aligned} \quad (4.3)$$

while the solvable and simple zero order problem is given by

$$\hat{H}_0\Phi_n = E_n^{(0)}\Phi_n \quad (4.4)$$

By projecting Equation 4.3 with $\langle\Phi_0|$ we get

$$\begin{aligned} \langle\Phi_n|\hat{H}_0|\Psi_n\rangle + \langle\Phi_n|\hat{V}|\Psi_n\rangle &= E_n\langle\Phi_n|\Psi_n\rangle \\ \rightarrow E_n &= \langle\Phi_n|\hat{H}|\Psi_n\rangle \\ \rightarrow \Delta E_n &= E_n - E_n^0 = \langle\Phi_n|\hat{V}|\Psi_n\rangle \end{aligned} \quad (4.5)$$

where we have used that

$$\langle\Phi_m|\Phi_n\rangle = \delta_{mn} \quad (4.6)$$

$$\langle \Psi_n | \Phi_n \rangle = \langle \Phi_n + \chi_n | \Phi_n \rangle = 1 \quad (4.7)$$

$$\langle \Psi_n | \Psi_n \rangle = 1 + \langle \chi_n | \chi_n \rangle. \quad (4.8)$$

This is called the intermediate normalisation assumption.

4.1.1 Energy- and Wavefunction Expansion

We now have need for the order parameter from λ Equation 4.2 as we expand the wavefunction and energy,

$$\begin{aligned} \Psi_n &= \Phi_n + \chi_n = \Psi_n^{(0)} + \lambda \Psi_n^{(1)} + \lambda^2 \Psi_n^{(2)} + \dots \quad (\Psi_n^{(0)} \equiv \Phi_n) \\ E_n &= E_n^{(0)} + \Delta E_n = E_n^{(0)} + \lambda E_n^{(1)} + \lambda^2 E_n^{(2)} + \dots \end{aligned} \quad (4.9)$$

We insert these expansions into the Schrödinger equation,

$$\begin{aligned} (\hat{H} - E_n) \Psi_n &= 0 \\ (\hat{H}_0 + \lambda \hat{V}) \Psi_n &= 0, \end{aligned} \quad (4.10)$$

resulting in

$$(\hat{H}_0 + \lambda \hat{V} - E_n^{(0)} - \lambda E_n^{(1)} - \lambda^2 E_n^{(2)} - \dots)(\Psi_n^{(0)} + \lambda \Psi_n^{(1)} + \lambda^2 \Psi_n^{(2)} + \dots) = 0. \quad (4.11)$$

Now we gather the coefficients of different powers of λ ,

$$(\hat{H}_0 - E_n^{(0)}) \Psi_n^{(0)} = 0 \quad (4.12)$$

$$(\hat{H}_0 - E_n^{(0)}) \Psi_n^{(1)} = (E_n^{(1)} - \hat{V}) \Psi_n^{(0)} \quad (4.13)$$

$$(\hat{H}_0 - E_n^{(0)}) \Psi_n^{(2)} = (E_n^{(1)} - \hat{V}) \Psi_n^{(1)} + E_n^{(2)} \Psi_n^{(0)} \quad (4.14)$$

...

$$(\hat{H}_0 - E_n^{(0)}) \Psi_n^{(m)} = (E_n^{(1)} - \hat{V}) \Psi_n^{(m-1)} + \sum_{l=0}^{m-2} E_n^{(m-l)} \Psi_n^{(l)}. \quad (4.15)$$

Where the last line gives a general m th-order equation. This equation can be simplified somewhat,

$$(E_n^{(0)} - \hat{H}_0) \Psi_n^{(m)} = \hat{V} \Psi_n^{(m-1)} - \sum_{l=0}^{m-1} E_n^{(m-l)} \Psi_n^{(l)}. \quad (4.16)$$

By applying $\langle \Phi_n |$ to each of the equations, we get expressions for $E_n^{(m)}$. For λ^1 (Equation 4.13) we get,

$$\begin{aligned} \langle \Phi_n | \hat{H}_0 - E_n^{(0)} | \Psi_n^{(1)} \rangle &= \langle \Phi_n | E_n^{(1)} - \hat{V} | \Phi_n \rangle \\ \langle (\hat{H}_0 - E_n^{(0)}) \Phi_n | \Psi_n^{(1)} \rangle &= \langle \Phi_n | E_n^{(1)} - \hat{V} | \Phi_n \rangle \\ \rightarrow E_n^{(1)} &= \langle \Phi_n | \hat{V} | \Phi_n \rangle = \hat{V}_{nn} \end{aligned} \quad (4.17)$$

Since we have an expression for $E_n^{(1)}$, we can solve the inhomogeneous differential equation for $\Psi_n^{(1)}$, by also requiring the intermediate normalisation condition $\langle \Phi_n | \Psi_n^{(1)} \rangle = 0$. For the general m th-order expression (Equation 4.15),

$$\begin{aligned} \langle \Phi_n | E_n^{(0)} - \hat{H}_0 | \Psi_n^{(m)} \rangle &= \langle \Phi_n | \hat{V} | \Psi_n^{(m-1)} \rangle - \sum_{l=0}^{m-1} E_n^{(m-l)} \langle \Phi_n | \Psi_n^{(l)} \rangle \\ E_n^{(m)} &= \langle \Phi_n^{(m)} | = \langle \Phi_n | \hat{V} | \Psi_n^{(m-1)} \rangle. \end{aligned} \quad (4.18)$$

In principle, we can obtain every next-order energy contribution $E_n^{(m)}$ from the previous-order wavefunctions $\Psi_n^{(m-1)}$ and then solve for $\Psi_n^{(m)}$.

4.1.2 The $2n + 1$ Wigner Rule

4.1.3 Projection Operators

We define the projection operators in terms of the zero-order wave functions,

$$\begin{aligned}\hat{P} &= |\Phi_0\rangle \langle \Phi_0| \\ \hat{Q} &= \hat{1} - \hat{P} = \sum_{i=1}^N |\Phi_i\rangle \langle \Phi_i|. \end{aligned} \quad (4.19)$$

The projection operators have the following convenient properties,

$$\begin{aligned}\hat{P}^2 &= |\Phi_0\rangle \langle \Phi_0| \Phi_0\rangle \langle \Phi_0| = |\Phi_0\rangle \langle \Phi_0| = \hat{P} \\ \hat{Q}^2 &= (1 - \hat{P})^2 = \hat{1} - \hat{P} - \hat{P} + \hat{P} = \hat{1} - \hat{P} = \hat{Q} \\ \hat{P}\hat{Q} &= \hat{Q}\hat{P} = 0 \\ [\hat{P}, \hat{H}_0] &= [\hat{Q}, \hat{H}_0] = 0\end{aligned} \quad (4.20)$$

If we write the wavefunction as a linear expansion in terms of Φ_i ,

$$\Phi = \sum_i a_i \Phi_i, \quad (4.21)$$

acting on it with the projection operators will yield

$$\hat{P}\Psi = \sum_i a_i |\Phi_0\rangle \langle \Phi_0| \Phi_i\rangle = \sum_i a_i |\Phi_0\rangle \delta_{0i} = a_0 \Phi_0. \quad (4.22)$$

In not so many greek letters, the operator \hat{P} will extract Φ_0 from Ψ , while \hat{Q} annihilates \hat{Q} ,

$$\hat{Q}\Psi = (\hat{1} - \hat{P})\Psi = \Psi - a_0 \Phi_0 = \sum_{i=1}^N a_i \Phi_i, \quad (4.23)$$

meaning we can write

$$\Psi = \hat{P}\Psi + \hat{Q}\Psi. \quad (4.24)$$

4.1.4 The Resolvent

Now follows what some considers a more elegant derivation of the perturbation equations, including the introduction of the *resolvent* of the unperturbed part of the Hamiltonian \hat{H}_0 .

Starting from a rearrangement of the Schrödinger equation,

$$\begin{aligned}(\hat{H}_0 + \hat{V})\Psi &= E\Psi, \\ \rightarrow -\hat{H}_0\Phi &= (\hat{V} - E)\Psi, \end{aligned} \quad (4.25)$$

we introduce a seemingline arbitrary parameter ζ by adding $\zeta\Phi$ to both sides,

$$(\zeta - \hat{H}_0)\Phi = (\hat{V} - E + \zeta)\Phi. \quad (4.26)$$

Next, we apply \hat{Q} to both sides,

$$\hat{Q}(\zeta - \hat{H}_0)\Psi = \hat{Q}(\hat{V} - E + \zeta)\Psi. \quad (4.27)$$

The right-hand side of this expression can be rewritten as,

$$\begin{aligned}\hat{Q}(\zeta - \hat{H}_0)\Psi &= \hat{Q}^2(\zeta - \hat{H}_0) = \hat{Q}(\zeta - \hat{H}_0)\hat{Q}\Psi \\ &= \sum_{i \neq 0} \sum_{j \neq 0} |\Phi_i\rangle \langle \Phi_i| \zeta - \hat{H}_0 |\Phi_j\rangle \langle \Phi_j|,\end{aligned}\quad (4.28)$$

Equation 4.27 is now

$$\hat{Q}(\zeta - \hat{H}_0)\hat{Q}\Psi = \hat{Q}(\hat{V} - E + \zeta)\Psi. \quad (4.29)$$

By restricting to choice of ζ , so they do not coincide with the eigenvalues of \hat{H}_0 in \hat{Q} -space, we ensure that the inverse of $\hat{Q}(\zeta - \hat{H}_0)\hat{Q}$ exists. This inverse is the *resolvent* of \hat{H}_0 ,

$$\hat{R}_0(\zeta) = \frac{\hat{Q}}{\zeta - \hat{H}_0} \equiv \sum_{i \neq 0} \sum_{j \neq 0} |\phi_i\rangle \langle \Phi_i| (\zeta - \hat{H}_0)^{-1} |\Phi_j\rangle \langle \Phi_j|. \quad (4.30)$$

The resolvent simplifies in the diagonal case to

$$\hat{R}_0(\zeta) = \sum_{i \neq 0} |\Phi_i\rangle \langle \Phi_i| (\zeta - E_j^{(0)})^{-1} |\Phi_j\rangle \langle \Phi_j| = \sum_{i \neq 0} \frac{|\Phi_i\rangle \langle \Phi_i|}{(\zeta - E_i^{(0)})}. \quad (4.31)$$

It is somewhat straightforward to prove that $\hat{R}_0(\zeta)$ is the inverse of $\hat{Q}(\zeta - \hat{H}_0)\hat{Q}$ in \hat{Q} -space,

$$\begin{aligned}\frac{\hat{Q}}{\zeta - \hat{H}_0} \hat{Q}(\zeta - \hat{H}_0)\hat{Q} &= \left(\sum_{i,j \neq 0} |\Phi_i\rangle \langle \Phi_i| (\zeta - \hat{H}_0)^{-1} |\Phi_j\rangle \langle \Phi_j| \right) \left(\sum_{k,l \neq 0} |\Phi_k\rangle \langle \Phi_k| (\zeta - \hat{H}_0) |\Phi_l\rangle \langle \Phi_l| \right) \\ &= \sum_{i,l \neq 0} |\Phi_i\rangle \langle \Phi_i| (\zeta - \hat{H}_0)^{-1} \left(\sum_{j \neq 0} |\Phi_j\rangle \langle \Phi_j| \right) (\zeta - \hat{H}_0) |\Phi_l\rangle \langle \Phi_l| \\ &= \sum_{i,l \neq 0} |\Phi_i\rangle \langle \Phi_i| (\zeta - \hat{H}_0)^{-1} (1 - |\Phi_0\rangle \langle \Phi_0|) (\zeta - \hat{H}_0) |\Phi_l\rangle \langle \Phi_l| \\ &= \sum_{i \neq 0} |\Phi_i\rangle \langle \Phi_i| = \hat{Q}.\end{aligned}\quad (4.32)$$

Applying the resolvent to both sides of Equation 4.29,

$$\begin{aligned}\hat{Q}\Psi &= \hat{R}_0(\zeta)(\hat{V} - E + \zeta)\Psi \\ \rightarrow \Psi &= \Phi_0 + \hat{R}_0(\zeta)(\hat{V} - E + \zeta)\Psi,\end{aligned}\quad (4.33)$$

which can be interpreted as a recursive relation for Ψ . Substituting the right-hand side into Ψ on the right-hand side repeatedly yields,

$$\Psi = \sum_{m=0}^{\infty} \{\hat{R}_0(\zeta)(\hat{V} - E + \zeta)\}^m \Phi_0. \quad (4.34)$$

The problem with this equation is that E , which is unknown, appears on the right-hand side. A question also arises regarding what to do with ζ . There are two common choices for ζ that give rise to two important theories,

$$\begin{aligned}\zeta &= E \leftarrow \text{Brillouin-Wigner Perturbation} \\ \zeta &= E_0^{(0)} \rightarrow -E + \zeta = -\Delta E \leftarrow \text{Rayleigh-Schrödinger Perturbation}\end{aligned}$$

4.2 [UNFINISHED] Brillouin-Wigner Perturbation Theory

Set $\zeta = E$ and get BWPT[6, 58].

4.3 [UNFINISHED] Rayleigh-Schrödinger Perturbation Theory

set $\zeta = E_n^{(0)}$ and get RSPT[48, 50].

Kapitel 5

Coupled Cluster

In the late 1950s Fritz Coester constructed a rigorous formal solution of the bound state Schrödinger equation as a set of single particle wave functions[9]. He wanted to find an expression for the wave operator ω , which transforms a zero-order wavefunction to the exact wave function,

$$\Psi = \Omega \Phi_0. \quad (5.1)$$

From Coester's solutions it would become apparent that the Rayleigh-Schrödinger perturbation expansions of the energy does not contain matrix elements representing the products of so-called unlinked diagram. In other words, one form of Ω is given a "linked-diagram expansion",

$$\Omega |\Phi_0\rangle = |\Phi_0\rangle = \sum_{k=1}^{\infty} \left((\hat{R}_0 \hat{W})^k |\Phi_0\rangle \right)_L. \quad (5.2)$$

a This is further underlined in discussions by John Hubbard[32] and Nicolaas Marinus Hugenholtz[33].

Conveniently, Ω may be written quite generally as

$$\Omega = e^{\hat{T}}, \quad \Psi = e^{\hat{T}} \Phi_0. \quad (5.3)$$

This exponential form has been come to be known as the Coupled Cluster ansatz, even though it is much more than a simple guess for the form of the exact wavefunction. To underline this point we quote Herman Kümmel: "Strange as it may be, in spite of the many successes of the coupled cluster method there is still a widespread belief that the underlying exponential structure is something artificial, accidental or an approximation only. This is why I want to make it clear that this feature is extremely natural - even necessary - on a very fundamental level, not necessarily connected with many-body theory"[34].

Throughout the 1950s and early 1960s, Coester and Kümmel developed the coupled cluster method together and proposed using the exponential-form wave operator as coupling between the shell-model state and the correct state vector for nuclear matter[10]. At the time, the method proved too computationally intensive. Specifically, the hard core potentials of nuclear physics leaves no freedom in truncating the set of coupled cluster equations. However, the method was picked up by Jiří Čížek who in 1966 reformulated the method for modelling of electron correlation in atoms and molecules[8]. Further development with Josef Paldus made the coupled cluster method one of the most successful¹ methods in quantum chemistry. Together with Isaiah Shavitt, Čížek and Paldus did the first *ab initio* computations with the method, which they called the coupled-pair many-electron-theory (MET)[42], as it can be interpreted as the perturbative variant of the many-electron-theory of Oktay Sinanoğlu[52].

¹At least one of the most prevalent

5.1 The Cluster Operator

Having established the form of the coupled cluster wavefunction as

$$|\Psi\rangle = e^{\hat{T}} |\Phi_0\rangle, \quad (5.4)$$

we now take a closer look at the cluster operator, which is divided into sub-operators

$$\hat{T} = \hat{T}_1 + \hat{T}_2 + \hat{T}_2 + \hat{T}_3 + \dots, \quad (5.5)$$

where the one-, two- and three-body operators are defined thusly,

$$\hat{T}_1 = \sum_{ai} t_i^a \{\hat{a}^\dagger \hat{i}\} \quad (5.6)$$

$$\hat{T}_2 = \frac{1}{(2!)^2} \sum_{ijab} t_{ij}^{ab} \{\hat{a}^\dagger \hat{i} \hat{b}^\dagger \hat{j}\} \quad (5.7)$$

$$\hat{T}_3 = \frac{1}{(3!)^2} \sum_{ijkabc} \{\hat{a}^\dagger \hat{i} \hat{b}^\dagger \hat{j} \hat{c}^\dagger \hat{k}\}, \quad (5.8)$$

where the coefficients $t_{ijk\dots}^{abc\dots}$ are commonly referred to as the coupled cluster *amplitudes*, and are coefficients to be determined. The strings of operators are automatically normal-ordered. The general m -body cluster operator is given by

$$\hat{T}_m = \frac{1}{(m!)^2} \sum_{\substack{ij\dots \\ ab\dots}} t_{ij\dots}^{ab\dots} \{\hat{a}^\dagger \hat{i} \hat{b}^\dagger \hat{j} \dots\}, \quad (5.9)$$

which produces an m -fold excitation. It is not necessary to include cluster-operators up to a infinite-fold excitation. Logically, the maximum excitation order is dictated by the number of electrons in the system n , such that $n \geq m$. Any higher-order excitation operator would eventually annihilate an unoccupied orbital, resulting in a zero-contribution. The prefactor $1/(m!)^2$ accounts for the redundancy created by unrestricted summations, as a permutation of any of the m hole or m particle indices will not produce a distinct contributions. Indeed, we have for example that

$$\hat{a}^\dagger \hat{i} \hat{b}^\dagger \hat{j} = -\hat{a}^\dagger \hat{j} \hat{b}^\dagger \hat{i} = -\hat{b}^\dagger \hat{a} \hat{i} \hat{j} = \hat{b}^\dagger \hat{j} \hat{a} \hat{i}, \quad (5.10)$$

and therefore we must also have that

$$t_{ij}^{ab} = -t_{ji}^{ab} = -t_{ij}^{ba} = t_{ji}^{ba}. \quad (5.11)$$

Hence, the $(2!)^2 = 4$ contributions of two hole indices, ab , and two particle indices, ij , will produce four equal terms, which is offset by the prefactor $1/4$.

The exponential wave operator $e^{\hat{T}}$ may be expanded as a Taylor series,

$$e^{\hat{T}} = 1 + \hat{T} + \frac{1}{2!} \hat{T}^2 + \frac{1}{3!} \hat{T}^3 + \dots \quad (5.12)$$

By including only single- and double excitations, $\hat{T}_{\text{CCSD}} = \hat{T}_1 + \hat{T}_2$, this expressions becomes

$$e^{\hat{T}_{\text{CCSD}}} = 1 + \hat{T}_1 + \hat{T}_2 + \frac{1}{2} \hat{T}_1^2 + \hat{T}_1 \hat{T}_2 + \frac{1}{2} \hat{T}_2^2 + \frac{1}{3!} \hat{T}_1^3 + \frac{1}{2} \hat{T}_1^2 \hat{T}_2 + \frac{1}{2} \hat{T}_1 \hat{T}_2^2 + \frac{1}{3!} \hat{T}_2^3 + \dots \quad (5.13)$$

Contributions to the wave function containing only a single cluster operator, \hat{T}_m , are called connected cluster contributions, while those containing products of cluster operators, $\hat{T}_{m_1}^\alpha \hat{T}_{m_2}^\beta$, are called disconnected cluster contributions.

This inclusion of only single- and double excitations is called “Coupled Cluster Singles Doubles”, elucidating the subscript CCSD[47]. The most common approximation in coupled cluster theory is the CCSD model. Here, the operator \hat{T}_2 describes the important electron-pair interaction and the \hat{T}_1 operator carries out the orbital relaxations induced by the field set up by electron-pair interactions.

Importance of different parts of the cluster operator

The most important contribution to the wave-function in quantum chemistry is undoubtedly \hat{T}_2 , because of the two-electron nature of the Hamiltonian. It describes the most important interaction of quantum chemistry, the electron-pair interaction. The inclusion of \hat{T}_1 and its products are relatively insensitive to the choice of basis set, as the operators $e^{\hat{T}_1}$ has the effect of transforming thereference state $|\Phi_0\rangle$ to another Slater determinant. This is known as Thouless theorem[57]. With very high electron-density, the three-particle operator \hat{T}_3 becomes important. Higher-order terms are usually of less and decreasing importance, but they can be of concern in special situations. For instance, the four-particle operator \hat{T}_4 is very important in nuclear physics. See for instance Helgaker et al[28] or Shavitt & Bartlett[51] for further discussion on this topic.

5.2 Coupled-Cluster Doubles (CCD)

As a good starting point for understanding the coupled cluster scheme and especially where the coupled-cluster equations come from, we now constrain the cluster operator to

$$\hat{T}_{\text{CCD}} = \hat{T}_2, \quad (5.14)$$

and completely derive the coupled cluster equations for this case. The CCD wave function includes all connected and disconnected clusters involving \hat{T}_2 only,

$$\Psi_{\text{CCD}} = e^{\hat{T}_2} \Phi_0 = \Phi_0 + \hat{T}_2 \Phi_0 + \frac{1}{2} \hat{T}_2^2 \Phi_0 + \frac{1}{3!} \hat{T}_2^3 \Phi_0 + \dots \quad (5.15)$$

There are several methods with which to arrive at the coupled-cluster equations and here we employ two of them for the coupled cluster doubles truncation. First, we use configuration-interaction techniques and the Slater-Condon rules (Appendix A) and second, we use the “algebraic method”, employing second quantisation and Wick’s theorem. A third way is with the aid of diagrams. A brief note on such diagrams can be found in Appendix B.

5.2.1 Configuration space derivation

We start from the CCD-constrained time-independent Schrödinger equation,

$$\hat{H} \Psi_{\text{CCD}} = E_{\text{CCD}} \Psi_{\text{CCD}}, \quad (5.16)$$

which we left project with the reference state,

$$\begin{aligned} \langle \Phi_0 | \hat{H} | \Psi_{\text{CCD}} \rangle &= \langle \Phi_0 | E_{\text{CCD}} | \Psi_{\text{CCD}} \rangle \\ &\rightarrow E_{\text{CCD}} = \langle \Phi_0 | \hat{H} | \Psi_{\text{CCD}} \rangle, \end{aligned}$$

where we have taken advantage of the intermediate normalisation, $\langle \Phi_0 | \Psi_{\text{CCD}} \rangle = 1$. We then insert the exponential expansion from the coupled cluster ansatz,

$$\begin{aligned} E_{\text{CCD}} &= \langle \Phi_0 | \hat{H}(1 + \hat{T}_2) | \Phi_0 \rangle \\ &= E_{\text{ref}} + \sum_{\substack{i>j \\ a>b}} \langle \Phi_0 | \hat{H} | \Phi_{ij}^{ab} \rangle t_{ij}^{ab} \\ &= E_{\text{ref}} + \sum_{\substack{i>j \\ a>b}} \langle ij | ab \rangle t_{ij}^{ab}. \end{aligned} \quad (5.17)$$

The energy expression will truncate here because no higher order terms will contribute. It is common to subtract E_{ref} to get,

$$\hat{H}_N \Psi_{\text{CCD}} = \Delta E_{\text{CCD}} \Psi_{\text{CCD}}, \quad (5.18)$$

where $\hat{H}_N = \hat{H} - E_{\text{ref}}$. Now follows a bunch of expressions intended to show the correspondence between coupled cluster- and perturbation theory,

$$\hat{H}_N = \hat{F} - \hat{U} + \hat{H}_2 - E_{\text{ref}} = \hat{H}_0 + \hat{F}^0 - \hat{U} + \hat{H}_2 - E_{\text{ref}}, \quad (5.19)$$

where,

$$\hat{H}_0 = \hat{F}^d = \sum_{\mu} \hat{f}_{\mu}^d, \quad \langle p | \hat{f}_{\mu}^d | q \rangle = \epsilon_p \delta_{pq} \quad (5.20)$$

$$\hat{F}^0 = \sum_{\mu} \hat{f}_{\mu}^0, \quad \langle p | \hat{f}^0 | q \rangle = (1 - \delta_{pq}) \langle p | \hat{f} | q \rangle \quad (5.21)$$

$$\hat{U} = \sum_{\mu} \hat{u}_{\mu}, \quad \langle p | \hat{u}_{\mu} | q \rangle = \sum_i \langle pi | qi \rangle \quad (5.22)$$

$$\hat{H}_2 = \sum_{\mu>\nu} \frac{1}{r_{\mu\nu}}, \quad E_{\text{ref}} = E_0 + E^{(1)}, \quad (5.23)$$

$$E_0 = \sum_i \epsilon_i, \quad E^{(1)} = -\frac{1}{2} \sum_{ij} \langle ij | ij \rangle. \quad (5.24)$$

In the canonical HF case we have $\hat{F}^0 = 0$ and $\hat{F}^d = \hat{F}$.

In order to compute the energy of the system we need the amplitudes t_{ij}^{ab} . Starting from the modified Schrödinger equation,

$$\hat{H}_N \Psi_{\text{CCD}} = \Delta E_{\text{CCD}} \Psi_{\text{CCD}}. \quad (5.25)$$

We left project with a doubly-excited Slater determinant, and insert for the CC ansatz,

$$\langle \Phi_{ij}^{ab} | \hat{H}_N e^{\hat{T}_2} | \Phi_0 \rangle = \Delta E_{\text{CCD}} \langle \Phi_{ij}^{ab} | e^{\hat{T}_2} | \Phi_0 \rangle \quad (5.26)$$

$$\langle \Phi_{ij}^{ab} | \hat{H}_N \left(1 + \hat{T}_2 + \frac{1}{2} \hat{T}_2^2 \right) | \Phi_0 \rangle = \Delta E_{\text{CCD}} t_{ij}^{ab}. \quad (5.27)$$

Here we have only expanded the exponential function up to the quadratic term. The next term in the series will triple-excite the bra Slater determinant, which will give a zero-contribution according to the Slater-Condon rules, because of two noncoincidences. Next we apply the Slater-Condon rules to the rest of the terms on the right-hand side, starting with just the normal-ordered Hamiltonian,

$$\langle \phi_{ij}^{ab} | \hat{H}_N | \Phi_0 \rangle = \langle ab | ij \rangle, \quad (5.28)$$

where only \hat{H}_2 contributes.

Next we look at the linear term,

$$\begin{aligned}
\langle \Phi_{ij}^{ab} | \hat{H}_N \hat{T}_2 | \Phi_0 \rangle &= \sum_{klcd} \langle \Phi_{ij}^{ab} | \hat{H}_N | \Phi_{kl}^{cd} \rangle \\
&= \langle \Phi_{ij}^{ab} | \hat{H}_0 - E_{\text{ref}} | \Phi_{ij}^{ab} \rangle t_{ij}^{ab} + \sum_{\substack{k>l \\ c>d}} \langle \Phi_{ij}^{ab} | \hat{F}^0 - \hat{U} | \Phi_{kl}^{cd} \rangle t_{kl}^{cd} \\
&\quad + \sum_{\substack{k>l \\ c>d}} \langle \Phi_{ij}^{ab} | \hat{H}_2 | \Phi_{kl}^{cd} \rangle t_{kl}^{cd} = L_0 + L_1 + L_2.
\end{aligned} \tag{5.29}$$

We are going to evaluate these terms one-by-one, starting with L_0 ,

$$\begin{aligned}
L_0 &= \langle \Phi_{ij}^{ab} | \hat{H}_0 - E_{\text{ref}} | \Phi_{ij}^{ab} \rangle = \langle \Phi_{ij}^{ab} | \hat{H}_0 - E_0 - E^{(1)} | \Phi_{ij}^{ab} \rangle \\
&= \left(-\varepsilon_{ij}^{ab} + \frac{1}{2} \sum_{kl} \langle kl | kl \rangle \right) t_{ij}^{ab},
\end{aligned} \tag{5.30}$$

where $\varepsilon_{ij}^{ab} = \varepsilon_i + \varepsilon_j - \varepsilon_a - \varepsilon_b$.

The next term,

$$L_1 = \sum_{\substack{k>l \\ c>d}} \langle \Phi_{ij}^{ab} | \hat{F}^0 - \hat{U} | \Phi_{kl}^{cd} \rangle t_{kl}^{cd}, \tag{5.31}$$

yields contributions if at least three of the indices k, l, c, d are equal to the indices i, j, a, b (we want one or zero noncoincidences). All the possible terms are,

$$L_1 = \begin{cases} -\sum_k u_{kk} t_{ij}^{ab} & \text{all indices equal} \\ -\sum_k (f_{jk}^0 - u_{jk}) t_{ik}^{ab} & \text{one hole index unequal} \\ +\sum_k (f_{ik}^0 - u_{ik}) t_{jk}^{ab} & \text{the other hole index unequal} \\ -\sum_c (f_{ac}^0 - u_{ac}) t_{ij}^{bc} & \text{one particle index unequal} \\ +\sum_c (f_{bc}^0 - u_{bc}) t_{ij}^{zc} & \text{the other particle index unequal.} \end{cases} \tag{5.32}$$

For the last linear term,

$$L_2 = \sum_{\substack{k>l \\ c>d}} \langle \Phi_{ij}^{ab} | \hat{H}_2 | \Phi_{kl}^{cd} \rangle t_{kl}^{cd}, \tag{5.33}$$

we require that at least two of the indices k, l, c, d are equal to the indices i, j, a, b , as we can do with at most two noncoincidences in the bra and the ket. For equality in both the hole indices or both the particle indices we have

$$cd = ab \rightarrow \sum_{k>l} \langle ij | kl \rangle t_{kl}^{ab} \tag{5.34}$$

$$kl = ij \rightarrow \sum_{c>d} \langle ab | cd \rangle t_{ij}^{cd}. \tag{5.35}$$

For one equality in both hole and particle index we have

$$-\sum_{kl} (\langle bk | cj \rangle t_{ik}^{ac} - \langle bk | ci \rangle t_{jk}^{ac} - \langle ak | cj \rangle t_{ik}^{bc} - \langle bk | ci \rangle t_{jk}^{ac}), \tag{5.36}$$

where the sign stems from the maximum coincidence permutations as dictated by the Slater-Condon rules. Most of the three- and four equal index terms are accounted for by the expression above, the remaining three-index equality terms are

$$- \sum_{kl} (\langle jl|kl \rangle t_{ik}^{ab} - \langle il|kl \rangle t_{jk}^{ab}) \quad (5.37)$$

$$+ \sum_{cl} (\langle bl|cl \rangle t_{ij}^{ac} - \langle al|cl \rangle t_{ij}^{bc}), \quad (5.38)$$

and there is one term for the case where all indices are equal,

$$\sum_{k>l} \langle kl|kl \rangle t_{ij}^{ab} = \frac{1}{2} \sum_{kl} \langle kl|kl \rangle t_{ij}^{ab}. \quad (5.39)$$

Difference between Coupled Cluster and Configuration Interaction

THIS BOX MAY BELONG SOMEWHERE ELSE (or may not be in a box)

Monkhorst[40] gives a general formula for transferring back and forth between CC operators \hat{T}_m and CI operators \hat{C}_m ,

$$\hat{C}_m = \sum_k \frac{1}{k!} \sum_{|m_\mu|} \delta(m_1 + m_2 + \dots + m_k, m) \prod_{\mu=1}^k \hat{T}_{m_\mu}, \quad (5.40)$$

where the second sum is over all sets of k m_μ -values that sum up to m . The first four of the terms are,

$$\hat{C}_1 = \hat{T}_1 \quad (5.41)$$

$$\hat{C}_2 = \hat{T}_2 + \frac{1}{2} \hat{T}_1^2 \quad (5.42)$$

$$\hat{C}_3 = \hat{T}_3 + \hat{T}_1 \hat{T}_2 + \frac{1}{3!} \hat{T}_1^3 \quad (5.43)$$

$$\hat{C}_4 = \hat{T}_4 + \frac{1}{2} \hat{T}_2^2 + \frac{1}{2} \hat{T}_2 \hat{T}_1^2 + \frac{1}{4!} \hat{T}_1^4. \quad (5.44)$$

For the CCSD and CISDTQ wavfunctions we have,

$$|\Psi_{\text{CCSD}}\rangle = \left(1 + \hat{T}_1 + \frac{1}{2} \hat{T}_1^2 + \frac{1}{3!} \hat{T}_1^3 + \hat{T}_2 + \frac{1}{2} \hat{T}_2^2 + \frac{1}{4!} \hat{T}_1^4 + \hat{T}_1 \hat{T}_2 \right) |\Phi_0\rangle \quad (5.45)$$

$$|\Psi_{\text{CISDTQ}}\rangle = \left(1 + \hat{C}_1 + \hat{C}_2 + \hat{C}_3 + \hat{C}_4 \right) |\Phi_0\rangle \quad (5.46)$$

which provides us with a relation between the two,

$$|\Psi_{\text{CCSD}}\rangle = |\Psi_{\text{CCSDTQ}}\rangle - (\hat{T}_3 + \hat{T}_4) |\Phi_0\rangle. \quad (5.47)$$

Moreover, we see that for a system of $n = 2$ particles, that

$$|\Psi_{\text{CCSD}}\rangle = |\Psi_{\text{CCSDTQ}}\rangle. \quad (5.48)$$

FILL IN MORE...

These last three- and four-index equality terms are expressible in terms of \hat{u} , and will cancel the first term in L_1 together with the \hat{u} term from L_0 . All terms so far are the same as in a

configuration interaction with doubles excitations (CID) computation. The difference between coupled cluster with doubles (CCD) and CID is the following extra quadratic terms,

$$Q = \frac{1}{2} \langle \Phi_{ij}^{ab} | \hat{H}_N \hat{T}_2^2 | \Phi_0 \rangle = \frac{1}{2} \sum_{\substack{k>l \\ c>d}} \sum_{\substack{m>n \\ e>f}} \langle \phi_{ij}^{ab} | \hat{H}_N | \Phi_{klmn}^{cdef} \rangle t_{kl}^{cd} t_{mn}^{ef}. \quad (5.49)$$

From this expression we will have a contribution only when four of the indices k, l, m, n, c, d, e, f are equal to i, j, a, b , and only \hat{H}_2 can contribute. After some algebraic acrobatics we'll find that this becomes

$$Q = \sum_{\substack{k>l \\ c>d}} \langle kl | cd \rangle [(t_{ij}^{ab} t_{kl}^{cd} + t_{ij}^{cd} t_{kl}^{ab}) - 2(t_{ik}^{ac} t_{jl}^{cd} + t_{ij}^{bd} t_{ij}^{bd}) - 2(t_{ik}^{ab} t_{jl}^{cd} + t_{ik}^{cd} t_{jl}^{ab}) + 4(t_{ik}^{ac} t_{jl}^{bd} + t_{ik}^{bd} t_{jl}^{ac})]. \quad (5.50)$$

From Equation 5.17 we see that

$$\Delta E_{\text{CCD}} = \sum_{\substack{i>j \\ a>b}} \langle ij | ab \rangle t_{ij}^{ab}, \quad (5.51)$$

and because the indices in Equation 5.50 are dummy variables we see that the first term here cancels with the right-hand side of Equation 5.27. Some algebraic massage after the initial acrobatic exercises leads to,

$$\begin{aligned} \varepsilon_{ij}^{ab} t_{ij}^{ab} &= \langle ab | ij \rangle + \frac{1}{2} \sum_{cd} \langle ab | cd \rangle t_{ij}^{cd} + \frac{1}{2} \sum_{kl} \langle ij | kl \rangle t_{kl}^{ab} \\ &\quad - \sum_{kl} (\langle bk | cj \rangle t_{ik}^{ac} - \langle bk | ci \rangle t_{jk}^{ac} - \langle ak | cj \rangle t_{ik}^{bc} + \langle ak | ci \rangle t_{jk}^{bc}) \\ &\quad - \sum_k \hat{f}_{jk}^0 t_{ik}^{ab} + \sum_k \hat{f}_{ik}^0 t_{jk}^{ab} + \sum_c \hat{f}_{bc}^0 t_{ij}^{ac} - \sum_c \hat{f}_{ac}^0 t_{ij}^{bc} \\ &\quad + \sum_{klcd} \langle kl | cd \rangle \left[\frac{1}{4} t_{ij}^{cd} t_{kl}^{ab} - \frac{1}{2} (t_{ij}^{ac} t_{kl}^{bd} + t_{ij}^{bd} t_{kl}^{ac}) \right. \\ &\quad \left. - \frac{1}{2} (t_{ik}^{ab} t_{jl}^{cd} + t_{ik}^{cd} t_{jl}^{ab}) + (t_{ik}^{ac} t_{jl}^{bd} + t_{ik}^{bd} t_{jl}^{ac}) \right], \end{aligned} \quad (5.52)$$

which is the CCD amplitude equations. This equation contains simultaneous algebraic expressions, contrary to CI. The equations must be solved iteratively, substituting t_{ij}^{ab} obtained in each iteration, into the quadratic terms for the next iteration.

5.2.2 Algebraic Derivation

In this derivation we make great use of second quantisation formalism and Wick's theorem. We start with the normal-ordered Hamiltonian,

$$\begin{aligned} \hat{H}_N &= (\hat{H}_0)_N + \hat{F}_N^0 + \hat{W} \\ &= \sum_p \varepsilon_p \{\hat{p}^\dagger \hat{p}\} + \sum_{p \neq q} f_{pq} \{\hat{p}^\dagger \hat{q}\} + \frac{1}{4} \sum_{pqrs} \langle pq | rs \rangle \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\}. \end{aligned} \quad (5.53)$$

The one-particle terms $(\hat{H}_0)_N$ and \hat{F}_N^0 can be combined by setting $\varepsilon_p = f_{pp}$, reducing the normal-ordered Hamiltonian to

$$\begin{aligned} \hat{H}_N &= \hat{F}_N + \hat{W} \\ &= \sum_{pq} f_{pq} \{\hat{p}^\dagger \hat{q}\} + \frac{1}{4} \sum_{pqrs} \langle pq | rs \rangle \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\}. \end{aligned} \quad (5.54)$$

First we want to find an expression for the energy,

$$\Delta E_{\text{CCD}} = \langle 0 | \hat{H}_N (1 + \hat{T}^2) | 0 \rangle = \langle 0 | \hat{H}_N \hat{T}_2 | 0 \rangle, \quad (5.55)$$

where only the vacuum expectation value of the product of the Hamiltonian and the doubles cluster operators gives a contributions, because the vacuum expectation value of just the Hamiltonian is zero. Inserting for the operators,

$$\Delta E_{\text{CCD}} = \sum_{\substack{i>j \\ a>b}} \langle 0 | \left[\sum_{pq} f_{pq} \{\hat{p}^\dagger \hat{q}\} + \frac{1}{4} \sum_{pqrs} \langle pq | rs \rangle \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \right] \{\hat{a}^\dagger \hat{b}^\dagger \hat{j} \hat{i}\} | 0 \rangle t_{ij}^{ab}. \quad (5.56)$$

Here the one-particle part will vanish as there is no manner one can contract all the operators in this term without using an internal contraction in the normal-ordered product. It is also useful to convert the first sum to an unrestricted sum,

$$\Delta E_{\text{CCD}} = \frac{1}{16} \sum_{ijab} \sum_{pqrs} \langle pq | rs \rangle \langle 0 | \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{a}^\dagger \hat{b}^\dagger \hat{j} \hat{i}\} | 0 \rangle t_{ij}^{ab}. \quad (5.57)$$

We contract the operators in the normal-ordered products,

$$\langle 0 | \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{a}^\dagger \hat{b}^\dagger \hat{j} \hat{i}\} + \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{a}^\dagger \hat{b}^\dagger \hat{j} \hat{i}\} \rangle \quad (5.58)$$

$$\begin{aligned} & + \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{a}^\dagger \hat{b}^\dagger \hat{j} \hat{i}\} + \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{a}^\dagger \hat{b}^\dagger \hat{j} \hat{i}\} | 0 \rangle \\ & = \delta_{pi} \delta_{qj} \delta_{sb} \delta_{ra} - \delta_{pi} \delta_{qj} \delta_{sa} \delta_{rb} \\ & \quad - \delta_{pj} \delta_{qi} \delta_{sb} \delta_{ra} + \delta_{pj} \delta_{qi} \delta_{sa} \delta_{rb}. \end{aligned} \quad (5.59)$$

All these products of delta functions give us a reduction in the sums and the CCD energy becomes,

$$\Delta E_{\text{CCD}} = \frac{1}{4} \sum_{ijab} \langle ij | ab \rangle t_{ij}^{ab}. \quad (5.60)$$

The natural next step is to find the amplitude equations,

$$\langle \Phi_{ij}^{ab} | \hat{H}_N \left(1 + \hat{T}_2 + \frac{1}{2} \hat{T}^2 \right) | 0 \rangle = \Delta E_{\text{CCD}} t_{ij}^{ab}. \quad (5.61)$$

We compute this expression in steps, starting with the lone normal-ordred Hamiltonian,

$$\langle \Phi_{ij}^{ab} | \hat{H}_N | 0 \rangle = \frac{1}{4} \sum_{pqrs} \langle 0 | \{\hat{a} \hat{b} \hat{j}^\dagger \hat{i}^\dagger\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} | 0 \rangle \langle pq | rs \rangle, \quad (5.62)$$

here we also have to compute a few contractions,

$$\langle 0 | \{\hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} + \{\hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \rangle \quad (5.63)$$

$$\begin{aligned} & + \{\hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} + \{\hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} | 0 \rangle \\ & = \delta_{ir} \delta_{js} \delta_{bq} \delta_{ap} - \delta_{ir} \delta_{js} \delta_{bp} \delta_{aq} \\ & \quad - \delta_{is} \delta_{jr} \delta_{bq} \delta_{ap} + \delta_{is} \delta_{jr} \delta_{bp} \delta_{aq}. \end{aligned} \quad (5.64)$$

This will leave us with a similar expression as the one in the energy equation,

$$\langle \Phi_{ij}^{ab} | \hat{H}_N | 0 \rangle = \langle ab | ij \rangle. \quad (5.65)$$

Now for the linear terms,

$$\begin{aligned} \langle \Phi_{ij}^{ab} | \hat{H}_N \hat{T}_2 | 0 \rangle &= \sum_{\substack{k>l \\ c>d}} \langle \phi_{ij}^{an} | \hat{H}_n \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} | 0 \rangle t_{kl}^{cd} \\ &= \frac{1}{4} \sum_{klcd} \langle \Phi_{ij}^{ab} | \hat{F}_N + \hat{W} | \Phi_{kl}^{cd} \rangle t_{kl}^{cd} \end{aligned} \quad (5.66)$$

Starting with the first term,

$$\begin{aligned} L_1 &= \frac{1}{4} \sum_{klcd} \langle \phi_{ij}^{ab} | \hat{F}_N | \phi_{kl}^{cd} \rangle t_{kl}^{cd} \\ &= \frac{1}{4} \sum_{klcd} \sum_{pq} p q f_{pq} \langle \phi_{ij}^{ab} | \{ \hat{p}^\dagger \hat{q} \} | \phi_{kl}^{cd} \rangle t_{kl}^{cd} \\ &= \frac{1}{4} \sum_{klcd} \sum_{pq} f_{pq} \langle 0 | \{ \hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a} \} \{ \hat{p}^\dagger \hat{q} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} | 0 \rangle t_{kl}^{cd} \end{aligned} \quad (5.67)$$

The product of normal-ordered operators must be contracted in such a way that tree and three operators in the first and last operators string are contracted with one another, and the two operators in the middle string is contracted with one operator in the last and first one. This provides us with $3 \times 3 \times 2 = 16$ possible contractions. Here are the first four contractions,

$$\begin{aligned} &\overbrace{\{ \hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a} \} \{ \hat{p}^\dagger \hat{q} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \}}^{(1)} + \overbrace{\{ \hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a} \} \{ \hat{p}^\dagger \hat{q} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \}}^{(2)} \\ &+ \overbrace{\{ \hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a} \} \{ \hat{p}^\dagger \hat{q} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \}}^{(3)} + \overbrace{\{ \hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a} \} \{ \hat{p}^\dagger \hat{q} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \}}^{(4)} \end{aligned} \quad (5.68)$$

$$\begin{aligned} &= \delta_{ik} \delta_{jl} \delta_{bd} \delta_{ap} \delta_{cq} + \delta_{ik} \delta_{jl} \delta_{ac} \delta_{bp} \delta_{dq} \\ &\quad - \delta_{ik} \delta_{jq} \delta_{bd} \delta_{ac} \delta_{pl} - \delta_{iq} \delta_{pk} \delta_{jl} \delta_{bd} \delta_{ac}. \end{aligned} \quad (5.69)$$

The last 12 contractions will be equivalent to these four, and thus we rid ourselves of the $\frac{1}{4}$ -prefactor, yielding

$$L_1 = \sum_c (f_{bc} t_{ij}^{ac} - f_{ac} t_{ij}^{bc}) + \sum_k (f_{ik} t_{jk}^{ab} - f_{jk} t_{ik}^{ab}). \quad (5.70)$$

Proceeding to the second linear term,

$$\begin{aligned} L_2 &= \frac{1}{4} \sum_{klcd} \langle \Phi_{ij}^{ab} | \hat{W} | \Phi_{kl}^{cd} \rangle t_{kl}^{cd} \\ &= \frac{1}{16} \sum_{pqrs} \sum_{klcd} \langle pq | rs \rangle \langle 0 | \{ \hat{j}^\dagger \hat{b} \hat{i}^\dagger \hat{a} \} \{ \hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} | 0 \rangle t_{kl}^{cd} \end{aligned} \quad (5.71)$$

Here there are many possible ways to contract the operators string, so it is convenient to label the different kinds of contractions. Subscript *a*-term consist of two hole-hole contractions, subscript *b*-terms consist of two particle-particle contractions and subscript *c*-terms consist of

one particle-hole and one hole-particle contractions,

$$\begin{aligned} L_{2a} &= \frac{1}{8} \sum_{pqrs} \sum_{klcd} \langle pq|rs \rangle \langle 0 | \overbrace{\{\hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger \hat{k} \hat{l}\}} | 0 \rangle t_{kl}^{cd} \\ &= \frac{1}{8} \sum_{pqrs} \sum_{cd} \langle pq|rs \rangle \langle 0 | \{\hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger\} | 0 \rangle t_{kl}^{cd} \end{aligned} \quad (5.72)$$

$$\begin{aligned} L_{2b} &= \frac{1}{8} \sum_{pqrs} \sum_{klcd} \langle pq|rs \rangle \langle 0 | \overbrace{\{\hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k}\}} | 0 \rangle t_{kl}^{cd} \\ &= \frac{1}{8} \sum_{pqrs} \sum_{kl} \langle pq|rs \rangle \langle 0 | \{\hat{i}^\dagger \hat{j}^\dagger\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{l} \hat{k}\} | 0 \rangle t_{kl}^{cd} \end{aligned} \quad (5.73)$$

$$\begin{aligned} L_{2c} &= \frac{1}{4} \sum_{pqrs} \sum_{klcd} \langle pq|rs \rangle \langle 0 | \overbrace{\{\hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k}\}} \\ &\quad + \overbrace{\{\hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k}\}} \\ &\quad + \overbrace{\{\hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k}\}} \\ &\quad + \overbrace{\{\hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k}\}} | 0 \rangle t_{kl}^{cd} \\ &= \frac{1}{4} \sum_{pqrs} \sum_{kc} \langle pq|rs \rangle \langle 0 | \{\hat{i}^\dagger \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{k}\} \\ &\quad - \{\hat{j}^\dagger \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{k}\} \\ &\quad - \{\hat{i}^\dagger \hat{b}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{k}\} \\ &\quad + \{\hat{j}^\dagger \hat{b}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{k}\} | 0 \rangle . \end{aligned} \quad (5.74)$$

The vacuum expectation value in L_{2a} can be evaluated as,

$$\langle 0 | \overbrace{\{\hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger\}} + \overbrace{\{\hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger\}} \quad (5.75)$$

$$\begin{aligned} &+ \overbrace{\{\hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger\}} + \overbrace{\{\hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger\}} | 0 \rangle \\ &= \delta_{bq} \delta_{ap} \delta_{sd} \delta_{rc} - \delta_{bq} \delta_{ap} \delta_{sc} \delta_{rd} \\ &\quad - \delta_{aq} \delta_{bp} \delta_{sd} \delta_{rc} + \delta_{aq} \delta_{bp} \delta_{sc} \delta_{rd} \end{aligned} \quad (5.76)$$

Inserting this result into the original expression and substituting to similar indicies will yield,

$$L_{2a} = \frac{1}{2} \sum_{cd} \langle ab|cd \rangle t_{ij}^{cd}. \quad (5.77)$$

A very similar computation will yield the following result for the next linear term,

$$L_{2b} = \frac{1}{2} \sum_{kl} \langle kl|ij \rangle t_{kl}^{ab}. \quad (5.78)$$

The last linear term is very different, however. INSERT SOMETHING HERE!

After long last, we have only the quadratic term to deal with,

$$Q = \frac{1}{8} \sum_{pqrs} \sum_{\substack{k>l \\ c>d}} \sum_{\substack{m>n \\ e>f}} \langle pq|rs \rangle \langle 0 | \{\hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a}\} \{\hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r}\} \{\hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k}\} \{\hat{e}^\dagger \hat{f}^\dagger \hat{n} \hat{m}\} | 0 \rangle t_{kl}^{dc} t_{mn}^{ef}. \quad (5.79)$$

In this expression there are no non-zero contractions between the third and fourth normal ordered operator string. We therefore need to contract operators in the first normal-ordered string with operators either in the third or four string, and the operator in the second string with the rest.

We start by contracting all operators in the first normal-ordered string with all the operators in the fourth normal-ordered string,

$$\begin{aligned} & \frac{1}{8} \sum_{pqrs} \sum_{\substack{k>l \\ c>d}} \sum_{\substack{m>n \\ e>f}} \langle pq|rs \rangle \langle 0 | \{ \hat{i}^\dagger \hat{j}^\dagger \hat{a}^\dagger \} \{ \hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} \{ \hat{e}^\dagger \hat{f}^\dagger \hat{n} \hat{m} \} | 0 \rangle t_{kl}^{cd} t_{mn}^{ef} \\ &= \frac{1}{8} \sum_{pqrs} \sum_{\substack{k>l \\ c>d}} \langle pq|rs \rangle \langle 0 | \{ \hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} | 0 \rangle t_{kl}^{cd} t_{ij}^{ab}. \end{aligned} \quad (5.80)$$

There are four possible ways to contract this last term, resulting in

$$\frac{1}{2} \sum_{\substack{k>l \\ c>d}} \langle kl|cd \rangle t_{kl}^{cd} t_{ij}^{ab}. \quad (5.81)$$

We get the same result by contracting the four operators in the first string with the four operators in the third string, cancelling the factor $\frac{1}{2}$, eventually yielding a result equal to $\Delta E_{\text{CCD}} t_{ij}^{ab}$, which we see by comparing this result to Equation 5.51.

There are four remaining reasonable classes in which to sort the permutations of contractions that remain;

- a the two hole operators in the first string are contracted with the third or fourth operator string, yielding equal results;
- b one hole and one particle operators in the first string are contracted with operators in the third string, the rest of the operators in the first string are contracted with operators in the fourth string;
- c two particle operators and one hole operator from the first string are contracted with operators in the third string, the last hole operator is contracted with an operator in the fourth string;
- d one particle operator and two hole operators are contracted with operators in the third string and the last particle operator with an operator in the fourth string.

The results for class a and class b are somewhat straight-forward to compute, giving the following,

$$\begin{aligned} Q_a &= \frac{1}{16} \sum_{pqrs} \sum_{klcd} \langle pq|rs \rangle \langle 0 | \{ \hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r} \} \{ \hat{l} \hat{k} \} \{ \hat{c}^\dagger \hat{d}^\dagger \} | 0 \rangle t_{ij}^{cd} t_{kl}^{ab} \\ &= \frac{1}{4} \sum_{klcd} \langle kl|rs \rangle t_{ij}^{cd} t_{kl}^{ab} \end{aligned} \quad (5.82)$$

$$\begin{aligned} Q_b &= \frac{1}{4} \sum_{pqrs} \sum_{klcd} \langle pq|rs \rangle \langle 0 | \{ \hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r} \} \{ \hat{c}^\dagger \hat{k} \} \{ \hat{d}^\dagger \hat{l} \} | 0 \rangle (t_{ik}^{ac} t_{jl}^{bd} - t_{ik}^{bc} t_{jl}^{ad}) \\ &= \sum_{klcd} \langle kl|cd \rangle (t_{ik}^{ac} t_{jl}^{bd} - t_{ik}^{bc} t_{jl}^{ad}) = \sum_{klcd} \langle kl|cd \rangle (t_{ik}^{ac} t_{jl}^{bd} - t_{ik}^{bd} t_{jl}^{ac}) \end{aligned} \quad (5.83)$$

The sets of terms for class c and d can each be generated in two distinct ways, dependent on the choice of the tree operators from the first operator string ($\hat{i}^\dagger \hat{a} \hat{b}$ or $\hat{j}^\dagger \hat{a} \hat{b}$ for c and $\hat{i}^\dagger \hat{j}^\dagger \hat{a}$

or $\hat{i}^\dagger \hat{j}^\dagger \hat{b}$ for d). In each case there are 16 possibilities; the three operators from the first string can be contracted with operators in both the third or fourth string in four ways and the remaining operators can be then be contracted in two ways. All these possibilities lead to equivalent results. For example, here is the first Q_c term,

$$\begin{aligned} & \frac{1}{8} \sum_{pqrs} \sum_{klcd} \sum_{mnef} \langle pq|rs \rangle \langle 0 | \{ \hat{i}^\dagger \hat{j}^\dagger \hat{b} \hat{a} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} \{ \hat{e}^\dagger \hat{f}^\dagger \hat{n} \hat{m} \} | 0 \rangle t_{kl}^{cd} t_{mn}^{ef} \\ &= -\frac{1}{8} \sum_{pqrs} \sum_{klcd} \langle pq|rs \rangle \langle 0 | \{ \hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} \{ \hat{l} \} | 0 \rangle t_{kj}^{cd} t_{li}^{ab} | 0 \rangle \end{aligned} \quad (5.84)$$

The remaining operators in this expression can be contracted in four ways,

$$\langle 0 | \{ \hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} \{ \hat{l} \} + \{ \hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} \{ \hat{l} \} \rangle \quad (5.85)$$

$$\begin{aligned} & + \{ \hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} \{ \hat{l} \} + \{ \hat{p}^\dagger \hat{q}^\dagger \hat{s} \hat{r} \} \{ \hat{c}^\dagger \hat{d}^\dagger \hat{l} \hat{k} \} \{ \hat{l} \} | 0 \rangle \\ &= \delta_{pl} \delta_{qk} \delta_{rd} \delta_{sc} - \delta_{pk} \delta_{ql} \delta_{rd} \delta_{sc} - \delta_{pl} \delta_{qk} \delta_{rc} \delta_{sd} + \delta_{pk} \delta_{ql} \delta_{rc} \delta_{sd} \end{aligned} \quad (5.86)$$

Algebra eventually leads to,

$$-\frac{1}{2} \sum_{klcd} \langle kl|cd \rangle t_{ik}^{ab} t_{jl}^{cd}. \quad (5.87)$$

A similar computations provides the second Q_c term,

$$-\frac{1}{2} \sum_{klcd} \langle kl|cd \rangle t_{ik}^{cd} t_{jl}^{ab} \quad (5.88)$$

These two terms give us,

$$Q_c = -\frac{1}{2} \sum_{klcd} \langle kl|cd \rangle (t_{ik}^{ab} t_{jl}^{cd} - t_{ik}^{cd} t_{jl}^{ab}) \quad (5.89)$$

Treating the class d terms gives,

$$Q_d = \frac{1}{2} \sum_{klcd} \langle kl|cd \rangle (t_{ij}^{ac} t_{kl}^{bd} - t_{ij}^{bd} t_{kl}^{ac}). \quad (5.90)$$

Combining all the quadratic terms will now yield the same as in Equation 5.50, and we can conclude that an algebraic derivation of the coupled cluster method is equivalent to the configuration space derivation.

5.3 The Coupled Cluster Equations

In general there is a more useful and compact approach that can be used to derive the coupled cluster equations, compared to the lengthy derivation of the CCD equations above. We start by inserting the coupled cluster wavefunctions into the time-independent Schrödinger equation,

$$\hat{H}_N e^{\hat{T}} |\Phi_0\rangle = \Delta E e^{\hat{T}} |\Phi_0\rangle. \quad (5.91)$$

In order to find an expression for the energy and amplitude equations one could try to left-project with $\langle \Phi_0 |$. This would propel us in the same direction as in the previous section, i.e.

Equation 5.17 and onwards. Instead, we multiply from the left with $e^{-\hat{T}}$ first, and then left-project with $\langle \Phi_0 |$,

$$\begin{aligned}\langle \Phi_0 | e^{-\hat{T}} \hat{H}_N e^{\hat{T}} | \Phi_0 \rangle &= \langle \Phi_0 | e^{-\hat{T}} \Delta E e^{\hat{T}} | \Phi_0 \rangle \\ \rightarrow \langle \Phi_0 | e^{-\hat{T}} \hat{H}_N e^{\hat{T}} | \Phi_0 \rangle &= \Delta E.\end{aligned}\quad (5.92)$$

Left-projecting with an excited state, $\langle \Phi_{ij\dots}^{ab\dots} |$ will give us expression for the corresponding amplitude $t_{ij\dots}^{ab\dots}$,

$$\langle \Phi_{ij\dots}^{ab\dots} | e^{-\hat{T}} \hat{H}_N e^{\hat{T}} | \Phi_0 \rangle = 0. \quad (5.93)$$

Now we have obtained a *non-Hermitian*², similarity-transformed Hamiltonian,

$$\mathcal{H} = e^{-\hat{T}} \hat{H}_N e^{\hat{T}}, \quad (5.94)$$

which has $|\Phi_0\rangle$ as right eigenfunction and E as the corresponding eigenvalue. Importantly, a similarity-transformation will not change the eigenvalue spectrum of the operator.

A benefit of the similarity-transformed Hamiltonians is that we can write the operators more explicitly by applying the Baker-Campbell-Hausdorff expansion[7, 4, 23],

$$\begin{aligned}e^{-\hat{B}} \hat{A} e^{\hat{B}} &= (1 - \hat{B} + \frac{1}{2} \hat{B}^2 - \frac{1}{3!} + \dots) \hat{A} (1 + \hat{B} + \frac{1}{2} \hat{B}^2 + \dots) \\ &= \hat{A} + (\hat{A} \hat{B} - \hat{B} \hat{A}) + \frac{1}{2} (\hat{A} \hat{B}^2 + 2 \hat{B} \hat{A} \hat{B} + \hat{B}^2 \hat{A}) \\ &\quad + \frac{1}{3!} (\hat{A} \hat{B}^3 - 3 \hat{B} \hat{A} \hat{B}^2 + 3 \hat{B}^2 \hat{A} \hat{B} - \hat{B}^3 \hat{A}) + \dots \\ &= \hat{A} + [\hat{A}, \hat{B}] + \frac{1}{2} \{(\hat{A} \hat{B} - \hat{B} \hat{A}) \hat{B} - \hat{B} (\hat{A} \hat{B} - \hat{B} \hat{A})\} \\ &\quad + \frac{1}{3!} \{[(\hat{A} \hat{B} - \hat{B} \hat{A}) \hat{B} - \hat{B} (\hat{A} \hat{B} - \hat{B} \hat{A})] \hat{B} \\ &\quad - \hat{B} [(\hat{A} \hat{B} - \hat{B} \hat{A}) \hat{B} - \hat{B} (\hat{A} \hat{B} - \hat{B} \hat{A})]\} + \dots \\ &= \hat{A} + [\hat{A}, \hat{B}] + \frac{1}{2} [[\hat{A}, \hat{B}], \hat{B}] + \frac{1}{3!} [[[\hat{A}, \hat{B}], \hat{B}], \hat{B}] + \dots\end{aligned}\quad (5.95)$$

Applying the Baker-Campbell-Hausdorff expansion to the similarity-transformed Hamiltonians yields

$$\begin{aligned}\mathcal{H} = e^{-\hat{T}} \hat{H}_N e^{\hat{T}} &= \hat{H}_N + [\hat{H}_N, \hat{T}] + \frac{1}{2} [[\hat{H}_N, \hat{T}], \hat{T}] + \frac{1}{3!} [[[\hat{H}_N, \hat{T}], \hat{T}], \hat{T}] \\ &\quad + \frac{1}{4!} [[[[\hat{H}_N, \hat{T}], \hat{T}], \hat{T}], \hat{T}].\end{aligned}\quad (5.96)$$

Notice the absence of an “and so on”-operator (...) in this expression. The Baker-Campbell-Hausdorff expansion for the electronic Hamiltonian, containing at most two-particle interactions, will terminate with the four-fold commutator.

By applying the generalised Wick’s theorem to the Baker-Campbell-Hausdorff expansion of the Hamiltonian in Equation 5.96, we will be confronted with a vast simplification. Applying the generalised Wick’s theorem to a commutator gives the following

$$[\hat{A}, \hat{B}] = \hat{A} \hat{B} - \hat{B} \hat{A} = \{\hat{A} \hat{B}\} + \overline{\{\hat{A} \hat{B}\}} - \{\hat{B} \hat{A}\} - \overline{\{\hat{B} \hat{A}\}}, \quad (5.97)$$

where \hat{A} and \hat{B} are normal-ordered operators, each with an even number of creation- and annihilation operators³. In this expression $\{\}$ denotes a normal-ordering of the operators inside

²We will show later that this non-Hermiticity is somewhat problematic.

³It is not a coincidence that both the normal-ordered Hamiltonian \hat{H}_N and the cluster operator \hat{T} satisfy these conditions

the braces and $\overline{\{\hat{A}\hat{B}\}}$ represents a sum of all normal-ordered products of operators in which there are one or more contractions between creation or annihilation operators in \hat{A} and those in \hat{B} . We must also have that

$$\{\hat{A}\hat{B}\} = \{\hat{B}\hat{A}\}, \quad (5.98)$$

since the two operators both contain an even number of creation- and annihilation operators. This means that what remains of Equation 5.97 is simply

$$[\hat{A}, \hat{B}] = \overline{\{\hat{A}\hat{B}\}} - \overline{\{\hat{B}\hat{A}\}}. \quad (5.99)$$

The general m -fold cluster operator T_m contains some number of creation operators $\hat{a}^\dagger, \hat{b}^\dagger \dots$ and hole operators \hat{i}, \hat{j}, \dots , and the only possible non-zero contractions are $\overline{\hat{a}\hat{b}^\dagger} = \delta_{ab}$ and $\overline{\hat{i}\hat{j}^\dagger} = \delta_{ij}$. Moreover, since the different cluster operators commute, no nonzero contractions exist between different \hat{T}_m operators. Ergo, in the nested commutators from Equation 5.96, we only see surviving terms between the Hamiltonian \hat{H}_N and one or more of the cluster operators \hat{T}_m . This accounts for the natural truncation at the four-fold commutator. In fact, we can rewrite the Baker-Campbell-Hausdorff-expanded similarity-transformed Hamiltonian as

$$\mathcal{H} = e^{-\hat{T}} \hat{H}_N e^{\hat{T}} = \hat{H}_N + \overline{\hat{H}_N \hat{T}} + \frac{1}{2} \overline{\hat{H}_N \hat{T} \hat{T}} + \frac{1}{3!} \overline{\hat{H}_N \hat{T} \hat{T} \hat{T}} + \frac{1}{4!} \overline{\hat{H}_N \hat{T} \hat{T} \hat{T} \hat{T}}, \quad (5.100)$$

where the very interesting notation combining a contraction line and an horizontal bar indicates a sum over all terms in which the Hamiltonian \hat{H}_N is connected by at least one contraction with each of the following cluster operators \hat{T} .

Disconnected clusters that on the form $\hat{T}_m \hat{T}_n$, which can be found in the coupled cluster wavefunction are not present in the Baker-Campbell-Hausdorff expansion of the similarity-transformed Hamiltonian. This is true also for the coupled cluster amplitude equations, which may be written

$$\langle \Phi_0 | e^{-\hat{T}} \hat{H}_N e^{\hat{T}} | \Phi_0 \rangle = \langle \Phi_0 | \hat{H}_N e^{\hat{T}} | \Phi_0 \rangle_C = \Delta E \quad (5.101)$$

$$\langle \Phi_{ij\dots}^{ab\dots} | e^{-\hat{T}} \hat{H}_N e^{\hat{T}} | \Phi_0 \rangle = \langle \Phi_{ij\dots}^{ab\dots} | \hat{H}_N e^{\hat{T}} | \Phi_0 \rangle_C = 0, \quad (5.102)$$

where the inclusion of only connected terms is underlined.

The CCSD equations take the form

$$\langle \Phi_0 | \hat{H}_N \left(\hat{T}_1 + \frac{1}{2} \hat{T}_1^2 + \hat{T}_2 \right) | \Phi_0 \rangle_C = \Delta E \quad (5.103)$$

$$\langle \Phi_i^a | \hat{H}_N \left(1 + \hat{T}_1 + \frac{1}{2} \hat{T}_1^2 + \frac{1}{3!} \hat{T}_1^3 + \hat{T}_1 \hat{T}_2 + \hat{T}_2 \right) | \Phi_0 \rangle_C = 0 \quad (5.104)$$

$$\langle \Phi_{ij}^{ab} | \hat{H}_N \left(1 + \hat{T}_1 + \frac{1}{2} \hat{T}_1^2 + \frac{1}{3!} \hat{T}_1^3 + \frac{1}{4!} \hat{T}_1^4 + \hat{T}_2 + \frac{1}{2} \hat{T}_2^2 + \hat{T}_1 \hat{T}_2 + \frac{1}{2} \hat{T}_1^2 \hat{T}_2 \right) | \Phi_0 \rangle_C = 0. \quad (5.105)$$

For CCSDT, the energy expression is the same, while the amplitude equations take the form

$$\langle \Phi_i^a | \hat{H}_N \left(1 + \hat{T}_1 + \frac{1}{2} \hat{T}_1^2 + \frac{1}{3!} \hat{T}_1^3 + \hat{T}_1 \hat{T}_2 + \hat{T}_2 + \hat{T}_3 \right) | \Phi_0 \rangle_C = 0 \quad (5.106)$$

$$\begin{aligned} \langle \Phi_{ij}^{ab} | \hat{H}_N \left(1 + \hat{T}_1 + \frac{1}{2} \hat{T}_1^2 + \frac{1}{3!} \hat{T}_1^3 + \frac{1}{4!} \hat{T}_1^4 + \hat{T}_2 \right. \\ \left. + \frac{1}{2} \hat{T}_2^2 + \hat{T}_1 \hat{T}_2 + \frac{1}{2} \hat{T}_1^2 \hat{T}_2 + \hat{T}_3 + \hat{T}_1 \hat{T}_3 \right) | \Phi_0 \rangle_C = 0 \end{aligned} \quad (5.107)$$

$$\begin{aligned} \langle \Phi_{ij}^{ab} | \hat{H}_N \left(\hat{T}_2 + \hat{T}_3 + \frac{1}{2} \hat{T}_2^2 + \hat{T}_1 \hat{T}_2 + \hat{T}_2 \hat{T}_3 + \hat{T}_1 \hat{T}_3 \right. \\ \left. + \frac{1}{2} \hat{T}_1^2 \hat{T}_2 + \frac{1}{2} \hat{T}_1 \hat{T}_2^2 + \frac{1}{2} \hat{T}_1^2 \hat{T}_3 + \frac{1}{3!} \hat{T}_1^3 \hat{T}_2 \right) | \Phi_0 \rangle_C = 0 \end{aligned} \quad (5.108)$$

the final result of the computation of these equations are provided in the appendices INSERT INTO THE APPENDICES!

5.4 [UNFINISHED] A Variational Formulation of Coupled Cluster

See Kvaal[36]

The Coupled Cluster method is very successful in computing energies, but computing other expectations values has been a problem. For instance we see that the way we compute the coupled cluster energy,

$$E_{CC} = \langle \Phi | e^{-\hat{T}} \hat{H} e^{\hat{T}} | \Phi \rangle, \quad (5.109)$$

is not the same as one would compute the energy of the system variationally,

$$\langle \hat{H} \rangle_{\text{var}} = \frac{\langle \Psi | \hat{H} | \Psi \rangle}{\langle \Psi | \Psi \rangle} = \frac{\langle \Phi | e^{\hat{T}^\dagger} \hat{H} e^{\hat{T}} | \Phi \rangle}{\langle \Phi | e^{\hat{T}^\dagger} e^{\hat{T}} | \Phi \rangle} \quad (5.110)$$

Moreover, the similarity transformed operators are not Hermitian. This can be showed by inference

$$\hat{T}_1^\dagger = \left(\sum_{ia} t_i^a \hat{a}^\dagger \hat{i} \right)^\dagger \sum_{ia} (t_i^a)^* \hat{i}^\dagger \hat{a} \neq \hat{T}_1, \quad (5.111)$$

from which it follows that

$$\left(e^{-\hat{T}} \hat{H} e^{\hat{T}} \right)^\dagger = (e^{\hat{T}})^\dagger \hat{H} (e^{-\hat{T}})^\dagger = e^{\hat{T}^\dagger} \hat{H} e^{-\hat{T}^\dagger} \neq e^{-\hat{T}} \hat{H} e^{\hat{T}}. \quad (5.112)$$

Variational computations as in Equation 5.110 has been attempted by Cizek[8] and Fink[16]. Regrettably, the coupled cluster exponential wavefunction is not a variationally optimal wavefunction, as it give rise to series expansions in the numerator and denominator in the expression for the variational expectation value. For a general operator \hat{O} , we have

$$\begin{aligned} \langle \hat{O} \rangle_{\text{var}} &= \frac{\langle \Psi | \hat{O} | \Psi \rangle}{\langle \Psi | \Psi \rangle} = \frac{\langle \Phi | e^{\hat{T}^\dagger} \hat{O} e^{\hat{T}} | \Phi \rangle}{\langle \Phi | e^{\hat{T}^\dagger} e^{\hat{T}} | \Phi \rangle} \\ &= \frac{\langle \Phi | [1 + \hat{T}^\dagger + \frac{1}{2!}(\hat{T}^\dagger)^2 + \frac{1}{3!}(\hat{T}^\dagger)^3 + \dots] \hat{O} [1 + \hat{T} + \frac{1}{2!}\hat{T}^2 + \frac{1}{3!}\hat{T}^3 + \dots] | \Phi \rangle}{\langle \Phi | [1 + \hat{T}^\dagger + \frac{1}{2!}(\hat{T}^\dagger)^2 + \frac{1}{3!}(\hat{T}^\dagger)^3 + \dots] [1 + \hat{T} + \frac{1}{2!}\hat{T}^2 + \frac{1}{3!}\hat{T}^3 + \dots] | \Phi \rangle}. \end{aligned} \quad (5.113)$$

In contrast with the expansions if the coupled cluster amplitude equations, which truncates naturally after products of four \hat{T} operators, the expansions for $e^{\hat{T}^\dagger}$ and $e^{\hat{T}}$ terminates only if the total excitation level represented by a product of \hat{T} operators exceed the number of electrons in the wavefunctions. This means that the number of terms and the computational effort required to compute expectation values in this way is usually very high.

An idea is to simply use a similar expression to the coupled cluster energy expression

$$\langle O \rangle_{\text{Goldstone}} = \langle \Phi | e^{-\hat{T}} \hat{O} e^{\hat{T}} | \Phi \rangle. \quad (5.114)$$

The problem with this expression, as well as with Equation 5.113, is that none of them conform with the Hellmann-Feynman theorem and the problem remains, the coupled cluster energy is arrived at non-variationally, and is therefore non-stationary.

5.4.1 The Hellmann-Feynman Theorem

The Hellmann-Feynman[14] theorem relates the first order change of total energy with respect to a parameter to the first order change of the Hamiltonian with respect to the same parameters,

$$\left. \frac{dE}{d\alpha} \right|_{\alpha=0} = \frac{\partial}{\partial t} \langle \Psi_\alpha | \hat{H} | \Psi_\alpha \rangle, \quad (5.115)$$

where Ψ is the exact state, variationally determined from the Hamiltonian of the system, and $\Psi_\alpha = N(\Psi + \alpha \delta \Psi)$ is variation of this state, implicitly dependent on the parameter α .

Proof of the Hellmann-Feynman theorem

Using the following conditions,

$$\hat{H}_\lambda |\psi_\lambda\rangle = E_\lambda |\psi_\lambda\rangle \quad (5.116)$$

$$\langle \psi_\lambda | \psi_\lambda \rangle = 1, \quad (5.117)$$

we prove

$$\frac{\partial E_\lambda}{\partial \lambda} = \langle \psi_\lambda | \frac{\partial \hat{H}}{\partial \lambda} | \psi_\lambda \rangle. \quad (5.118)$$

Now,

$$E_\lambda = \langle \psi_\lambda | \hat{H} | \psi_\lambda \rangle = \int \psi_\lambda \hat{H} \psi_\lambda^* dr \quad (5.119)$$

whence,

$$\begin{aligned} \frac{\partial E_\lambda}{\partial \lambda} &= \int \psi_\lambda \frac{\partial \hat{H}}{\partial \lambda} \psi_\lambda^* dr + \int \frac{\partial \psi_\lambda}{\partial \lambda} \hat{H} \psi_\lambda^* dr + \int \psi_\lambda \hat{H} \frac{\partial \psi_\lambda^*}{\partial \lambda} dr \\ &= \int \psi_\lambda \frac{\partial \hat{H}}{\partial \lambda} \psi_\lambda^* dr + E_\lambda \int \frac{\partial \psi_\lambda}{\partial \lambda} \psi_\lambda^* dr + E_\lambda \int \psi_\lambda \frac{\partial \psi_\lambda^*}{\partial \lambda} dr \\ &= \int \psi_\lambda \frac{\partial \hat{H}}{\partial \lambda} \psi_\lambda^* dr + E_\lambda \frac{\partial}{\partial \lambda} \langle \psi_\lambda | \psi_\lambda \rangle = \langle \psi_\lambda | \frac{\partial \hat{H}}{\partial \lambda} | \psi_\lambda \rangle. \end{aligned} \quad (5.120)$$

By treating an observable of the system as a perturbation of the Hamiltonian,

$$\hat{H}'(\alpha) = \hat{H} + \alpha \hat{V},$$

the Hellman-Feynman theorem provides us with a way to evaluate the expected value of this observable if we have the exact wavefunction and energy,

$$\left. \frac{dE}{d\alpha} \right|_{\alpha=0} = \frac{\partial}{\partial \alpha} \langle \Psi_\alpha | \hat{H} + \alpha \hat{V} | \Psi_\alpha \rangle = \langle \hat{V} \rangle. \quad (5.121)$$

The problem with some computational techniques, like the coupled cluster method, is that the final energy is not variationally determined (non-stationary), and we cannot invoke the Hellmann-Feynman theorem to simplify computation of molecular properties. At first, it would appear that one would have to resort to a more cumbersome computation, like the expansion of cluster operators above (Equation 5.113). But fortunately, there exists a way to reformulate the energy function of a non-variational wavefunction in such a way that the energy is stationary with respect to the variables of the new formulation.

Consider an energy that depends on two sets of parameters. The parameter α which describes a perturbation and the parameters λ which describe the wavefunction. The optimal energy $E(\alpha)$ is obtained by an optimised set of parameters λ^* , which are inserted into the energy function $E(\alpha, \lambda)$;

$$E(\alpha) = E(\alpha, \lambda^*), \quad (5.122)$$

the values for α and λ^* are obtained as the solution to some set of equations

$$\mathbf{f}(\alpha, \lambda^*) = 0 \quad \forall \alpha, \quad (5.123)$$

For *variational* wavefunctions, this condition corresponds to the stationarity requirement,

$$\left. \frac{\partial E_{\text{var}}(\alpha, \lambda)}{\partial \lambda} \right|_{(\lambda=\lambda^*)} = 0 \quad \forall \alpha, \quad (5.124)$$

but not for *non-variational* wavefunctions. Writing out this derivative yields,

$$\frac{dE(\alpha)}{d\alpha} = \left. \frac{dE(\alpha, \lambda)}{d\alpha} \right|_{(\lambda=\lambda^*)} = \left. \frac{\partial E(\alpha, \lambda)}{\partial \alpha} \right|_{(\lambda=\lambda^*)} + \left. \frac{\partial E(\alpha, \lambda)}{\partial \lambda} \right|_{(\lambda=\lambda^*)} \cdot \left. \frac{\partial \lambda}{\partial \alpha} \right|_{(\lambda=\lambda^*)}. \quad (5.125)$$

For a variational wavefunction, the last term will vanish due to the stationarity condition in Equation 5.124. This would leave us with

$$\frac{dE_{\text{var}}(\alpha)}{d\alpha} = \left. \frac{\partial E(\alpha, \lambda)}{\partial \alpha} \right|_{(\lambda=\lambda^*)}, \quad (5.126)$$

i.e. that the total derivative corresponds to the partial derivative. This means that if the variational energy corresponds to an expectation value $E_{\text{var}}(\alpha, \lambda) = \langle \lambda | \hat{H}(\alpha) | \lambda \rangle$, and the perturbed system is described by the Hamiltonian $\hat{H}(\alpha) = \hat{H} + \alpha \hat{V}$, we recover the presumed expression

$$\left. \frac{dE(\alpha, \lambda)}{d\alpha} \right|_{(\alpha=0)}, \quad (5.127)$$

in accordance with first-order perturbation theory and the Hellmann-Feynmann theorem.

But if we look at nonvariational energies, Equation 5.125, will not simplify to just the partial derivative, since the stationarity condition does not hold. What we do is replace the now nonvariational function $E(\alpha, \lambda)$ by a new function $L(\alpha, \lambda, \bar{\lambda})$ with a stationary point $(\lambda^*, \bar{\lambda}^*)$ that satisfies the nonvariational condition Equation 5.123, and whose values at this point correspond to the optimal energy. Indeed, we apply Lagrange's method of undetermined multipliers, by regarding the energy $E(\alpha, \lambda)$ as an *unconstrained* optimisation problem, but subject to the constraints of the variational parameters λ , which satisfy Equation 3.17;

$$L(\alpha, \lambda, \bar{\lambda}) = E(\alpha, \lambda) + \bar{\lambda} \cdot \mathbf{f}(\alpha, \lambda). \quad (5.128)$$

A necessary condition for the optimum Lagrange multipliers $\bar{\lambda}^*$ to be unique is that the the Jacobian of \mathbf{f} , $\mathcal{J} \equiv \partial \mathbf{f}(\alpha, \lambda) / \partial \lambda$ is non-singular and invertible.

5.4.2 The Lagrangian Formulation of Coupled Cluster

As we outlined in the previous section, the solution to making the coupled cluster theory into a variational theory is to find a set of equations which are zero for a set of parameters (Equation 5.123). These parameters should in turn provide the optimal energy by insertion into the expression for energy. Luckily, Helgaker and Jørgensen[26, 27] had the insight to realise that we are already given such a set of parameters and equations in the formulation of coupled cluster, namely the amplitudes and the amplitude equations respectively. The Hellmann-Feynman theorem will be baked into the very definition of such a expectation value functional,

$$\langle \hat{O} \rangle_{\text{H-F}} = \mathcal{L}_O(\alpha^*, \lambda^*, \bar{\lambda}^*) = E(\alpha^*, \lambda^*, \bar{\lambda}^*) + \bar{\lambda}^* \cdot \mathbf{f}(\alpha^*, \lambda^*). \quad (5.129)$$

This equation is essentially a restatement of Equation 5.128, with the optimal parameters.

More specifically, we simplify the notation in some measure and state the coupled cluster energy Lagrangian,

$$\mathcal{L}_{\hat{H}}(t, \lambda) = \langle \Phi | e^{-\hat{T}} \hat{H} e^{\hat{T}} | \Phi \rangle + \sum_{\mu} \lambda_{\mu} \langle \Phi | X_{\mu}^{\dagger} e^{-\hat{T}} \hat{H} e^{\hat{T}} | \Phi \rangle = \langle \Phi | (1 + \Lambda) e^{-\hat{T}} \hat{H} e^{\hat{T}} | \Phi \rangle, \quad (5.130)$$

where we have introduced $\Lambda = \sum_{\mu} X_{\mu}^{\dagger}$. Here, X_{μ}^{\dagger} is a general relaxation operator, for instance $\hat{X}_1^{\dagger} = \{\hat{i}\hat{a}^{\dagger}\}$. So Λ written out is

$$\Lambda = \sum_{ia} \lambda_a^i \hat{i}^{\dagger} + \frac{1}{2!^2} \sum_{ijab} \lambda_{ab}^{ij} \hat{i}^{\dagger} \hat{a} \hat{j}^{\dagger} \hat{a} + \dots \quad (5.131)$$

The coupled cluster Lagrangian in Equation 5.130 can be rewritten with the use of density operators,

$$\mathcal{L}_{\hat{H}}(t, \lambda) = \text{tr}\{\hat{H}\hat{\rho}\}, \quad \hat{\rho} = e^{\hat{T}} |\Phi\rangle\langle\Phi| (1 + \Lambda) e^{-\hat{T}}, \quad (5.132)$$

in a pure state description. We check to see if the attributes of the density operator endures,

$$\begin{aligned} \hat{\rho}^2 &= e^{\hat{T}} |\Phi\rangle\langle\Phi| (1 + \Lambda) e^{-\hat{T}} e^{\hat{T}} |\Phi\rangle\langle\Phi| (1 + \Lambda) e^{-\hat{T}} \\ &= e^{\hat{T}} |\Phi\rangle\langle\Phi| (1 + \Lambda) e^{-\hat{T}} + e^{\hat{T}} |\Phi\rangle\langle\Phi| \Lambda e^{-\hat{T}} e^{\hat{T}} |\Phi\rangle\langle\Phi| (1 + \Lambda) e^{-\hat{T}} \\ \text{Tr}\{\hat{\rho}\} &= \sum_{pq} \langle\phi_p| e^{\hat{T}} |\phi_q\rangle\langle\phi_q| (1 + \Lambda) e^{-\hat{T}} |\phi_p\rangle = \sum_{pq} \delta_{pq} = 1 \end{aligned}$$

NOT ENTIRELY SURE THAT THE LAST ONE IS GOOD. We see however, that another problem has presented itself, as the density operator is non-Hermitian. This leads us to the *bivariational*, Hellmann-Feynman conforming framework developed by Arponen[3].

5.4.3 The Bivariational Principle

Arponen approached the coupled cluster problem by employing a very general form of the variational principle called the bivariational principle. Letting \hat{H} , be a (possibly non-Hermitian) operator over Hilbert space \mathcal{H} , the bivariational expectation functional is defined by

$$\mathcal{E}_{\hat{H}} : \mathcal{H}' \times \mathcal{H} \rightarrow \mathbb{C}, \quad \mathcal{E}_{\hat{H}}(\tilde{\Psi}, \Psi) = \frac{\langle \tilde{\Psi} | \hat{H} | \Psi \rangle}{\langle \tilde{\Psi} | \Psi \rangle} = \frac{\text{tr}\{\hat{H}\hat{\rho}\}}{\text{tr}\{\hat{\rho}\}}. \quad (5.133)$$

The main difference from the traditional and usual variational principle is that $\langle \tilde{\Psi} |$ and $|\Psi\rangle$ are treated as independent elements of the Hilbert space, and $\hat{\rho} = |\Psi\rangle\langle\tilde{\Psi}|$. In the usual variational principle, we have $\langle \tilde{\Psi} | \equiv |\Psi\rangle$, which are *not* independent. Nevertheless, since the Hamiltonian \hat{H} is Hermitian, $\langle \tilde{\Psi} |$ and $|\Psi\rangle$ can be treated independent in the derivations of stationary conditions, which are that the left- and right eigenvalues of $\langle \tilde{\Psi} |$ and $|\Psi\rangle$, respectively, must be the same, id est

$$\hat{H} |\Psi\rangle = E |\Psi\rangle, \quad \langle \tilde{\Psi} | \hat{H} = \langle \tilde{\Psi} | E. \quad (5.134)$$

Here $E = \mathcal{E}_{\hat{H}}(\tilde{\Psi}, \Psi)$ is the value at the stationary point.

We transition to coupled cluster theory by inserting the coupled cluster exponential wave functions, $|\Psi\rangle = e^{\hat{T}} |\Phi\rangle$ and $\langle \tilde{\Psi} | = \langle \Phi | e^{\tilde{T}}$, where $\tilde{T} = \tilde{t} X^{\dagger}$ are some general relaxation operator. The bivariational functional becomes

$$\mathcal{E}_{\hat{H}} = \frac{\langle \Phi | e^{\tilde{T}} \hat{H} e^{\hat{T}} | \Phi \rangle}{\langle \Phi | e^{\tilde{T}} e^{\hat{T}} | \Phi \rangle} \quad (5.135)$$

Varying this functional over all untruncated excitation and relaxation operators, \hat{T} and \tilde{T} , is the foundation of variational coupled cluster theory[5], which is equivalent to full configuration interaction within the given single-particle basis set.

Now we wish to show that Arponen's framework corresponds to that of Helgaker and Jørgensen. We simplify the expression by performing a variable change $(\hat{T}, \tilde{T}) \rightarrow (\hat{T}, \hat{S})$, where S is a new relaxation operator. We start by introducing

$$\langle \omega | = \frac{\langle \tilde{\Psi} | e^{\hat{T}}}{\langle \tilde{\Psi} | \Psi \rangle}, \quad (5.136)$$

which satisfies $\langle \omega | \Phi \rangle = 1$, implying that there must exist an operator $\hat{S} = sX^\dagger$, such that $\langle \omega | = \langle \Phi | e^{\hat{S}}$. Then we can write,

$$\frac{\langle \tilde{\Psi} | e^{\hat{T}}}{\langle \tilde{\Psi} | \Psi \rangle} = \langle \Psi | e^{\hat{S}}, \rightarrow \langle \tilde{\Psi} | = \langle \tilde{\Psi} | \Psi \rangle \langle \Phi | e^{\hat{S}} e^{-\hat{T}}. \quad (5.137)$$

This enables us to rewrite the bivariational principle (Equation 5.135) to

$$\mathcal{E}_{\hat{H}} = \langle \Phi | e^{\hat{S}} e^{-\hat{T}} \hat{H} e^{\hat{T}} | \Phi \rangle, \quad (5.138)$$

which is an exact functional if \hat{T} and \hat{S} are not truncated. Comparing this expression to the coupled cluster Lagrangian in Equation 5.130, we can only conclude that our seemingly serendipitous algebra acrobatics has revealed that $e^{\hat{S}} = 1 + \Lambda$. Truthfully, we have strong indication the coupled cluster bivariational functional (Equation 5.135) is the same as the the coupled cluster Lagrangian (Equation 5.130). As a sidenote, pruning the expression in Equation 5.138 to only include single and double excitations will yield Arponen's *extended coupled cluster* (ECC) method.

First order conditions of the coupled cluster energy Lagrangian in Equation 5.130 gives us a new set of amplitude equations,

$$\frac{\partial}{\partial \lambda_\mu} \mathcal{L}(t, \lambda) = \langle \Phi_{X_\mu} | e^{-\hat{T}} \hat{H} e^{\hat{T}} | \Phi \rangle = 0 \quad (5.139)$$

$$\frac{\partial}{\partial t_\mu} \mathcal{L}(t, \lambda) = \langle \Phi | (1 + \Lambda) e^{-\hat{T}} [\hat{H}, X_\mu] e^{\hat{T}} | \Phi \rangle = 0. \quad (5.140)$$

Under constrained optimisation all partial derivatives vanish at the same point,

$$\left. \frac{\partial \mathcal{L}}{\partial \lambda_\mu} \right|_{t=t^*} = 0, \quad \left. \frac{\partial \mathcal{L}}{\partial t_\mu} \right|_{(t, \lambda) = (t^*, \lambda^*)} = 0, \quad \forall X_\mu. \quad (5.141)$$

What we have arrived at are amplitude equations both for the “bra part” and the “ket part” of the problem, which we refer to as the λ amplitude equations (Equation 5.140) and the τ amplitude equations (Equation 5.140), respectively. Notice that the τ amplitude equations only depend on τ , whilst the λ equations depend both on τ and λ . This means that the τ amplitude equations are solved iteratively first, and then the λ amplitudes are solved similarly. The full equations are given in appendix (LINK TO APPENDIX).

5.5 [UNFINISHED] Generealisation in Time

We now define a time-dependent generalisation of the bivariational principle (Equation 5.133). This is similar to the usual time-dependent action functional and the time-dependent Schrödinger equation can be recovered from it,

$$\mathcal{S}[\Psi'(\cdot), \Psi(\cdot)] = \int_0^T dt \frac{\langle \Psi'(t) | \left(i\hbar \frac{\partial}{\partial t} - \hat{H} \right) | \Psi(t) \rangle}{\langle \Psi'(t) | \Psi(t) \rangle}. \quad (5.142)$$

Functionals like these are quite common throughout the historical literature on quantum mechanics, appearing as early as in Dirac[12]. The integral of the functional depends on all history for the system in question. Under normal variation of the functional. By applying the principle of least action, requiring that the functional is stationary, $\delta\mathcal{S} = 0$, under all variations of $\langle\Psi|$ and $|\Psi\rangle$ and vanishing in the endpoints $t = 0$ and $t = T$, gives us the following conditions

$$i\hbar \frac{\partial}{\partial t} |\Psi(t)\rangle = \hat{H} |\Psi(t)\rangle \quad -i\hbar \frac{\partial}{\partial t} \langle\Psi'| = \langle\Psi'| \hat{H}.$$

By a specific parametrisation of $\langle\Psi'|$, such that $\langle\Psi'|\Psi\rangle = 1$ we have indeed recovered the familiar time-dependent Schrödinger equation.

Instead of venturing down this path, we will presuppose that it is possible that $\langle\Psi'|\Psi\rangle \neq 1$. Indeed, that $\langle\Psi'|$ and $|\Psi\rangle$ are independent. This means we must enact Arponen's[3] Hellmann-Feynman conforming bivariational principle, where the energy expectation functional is given by

$$\mathcal{E}_{\hat{H}}(\tau^\dagger, \tau, \tilde{\Phi}, \Phi) = \frac{\langle \tilde{\Phi} | e^{\hat{T}^\dagger} \hat{H} e^{\hat{T}} | \Phi \rangle}{\langle \tilde{\Phi} | e^{\hat{T}^\dagger} e^{\hat{T}} | \Phi \rangle}. \quad (5.143)$$

We perform a variable change $(T', T) \rightarrow (\lambda, T)$, similarly to the section above, and introduce

$$\langle \tilde{\Psi} | = \frac{\langle \Psi^\dagger |}{\langle \Psi^\dagger | \Psi \rangle} = \langle \tilde{\Phi} | (1 + \Lambda) e^{\hat{T}}, \quad (5.144)$$

Where Λ is the same as in Equation 5.131. The bivariational energy expectation functional in Equation 5.143 now becomes

$$\mathcal{E}_{\hat{H}}(\lambda, \tau, \tilde{\Phi}, \Phi) = \langle \tilde{\Phi} | (\hat{1} + \lambda) e^{-\hat{T}} \hat{H} e^{\hat{T}} | \Phi \rangle. \quad (5.145)$$

Disregarding the difference in $\tilde{\Phi}$ and Φ , this expression is the same as the coupled cluster expectation functional in Equation 5.138, where the interpretation is that the λ s are Lagrange multipliers for a constrained energy minimisation problem. This is not the interpretation here, as the λ -part of the problem is seen as equally important.

We are now assuming biorthogonality in orbitals, $\langle \tilde{\phi}_p | \phi_q \rangle = \delta_{pq}$, but independence of bra and ket states otherwise. For a full Slater determinant state consisting of these orbitals, we have

$$\langle \tilde{\phi}_{p_1} \dots \tilde{\phi}_{p_n} | \phi_{q_1} \dots \phi_{q_n} \rangle = \delta_{p_q q_1} \dots \delta_{p_n q_n}. \quad (5.146)$$

The second quantised operators associated with these Slater determinants are defined through

$$|\phi_{q_1} \dots \phi_{q_n}\rangle \equiv c_{p_1}^\dagger \dots c_{p_n}^\dagger | \rangle \quad \langle \tilde{\phi}_{p_1} \dots \tilde{\phi}_{p_n} | = \langle | \tilde{c}_{q_n} \dots \tilde{c}_{q_1}. \quad (5.147)$$

These creation- and annihilation operators can furthermore be defined by,

$$c_p^\dagger = \int \phi_p(\mathbf{x}) \Psi^\dagger(\mathbf{x}) d\mathbf{x} \quad \tilde{c}_p^\dagger = \int \tilde{\phi}_p(\mathbf{x}) \Psi(\mathbf{x}) d\mathbf{x}, \quad (5.148)$$

where Ψ^\dagger and Ψ are field creation- and annihilation operators. These second quantised operators are subject to the anticommutator relation,

$$\{\tilde{c}_p, c_q^\dagger\} \equiv \tilde{c}_p c_q^\dagger + c_q^\dagger \tilde{c}_p \stackrel{!}{=} \langle \tilde{\phi}_p | \phi_q \rangle = \delta_{pq} = \delta_{pq}. \quad (5.149)$$

Implementation: Quantum Systems

For a quantum system to be studied on the computer it is necessary to make a distinction for what defines the system. One must therefore undergo the mathematical procedure of defining a finite basis sets that defines the quantum system under scrutiny when dealing with the electronic problem.

Here we present the `quantum_system` python module, designed to provide basis sets for one- and two-dimensional quantum dots. The two-dimensional quantum dot can also be modelled with a constant, homogeneous magnetic field; and as a double quantum dot. Moreover, the module includes an option for constructing a custom system which can be interfaced with popular quantum chemistry packages PySCF[55] and Psi4[43].

The `quantum_system` module can be installed from github with `pip` by the following command,

```
pip install git+https://github.com/Schoyen/quantum-systems.git
```

The same task can of course be accomplished by more commands,

```
git clone https://github.com/Schoyen/quantum-systems.git
cd quantum-systems
pip install .
```

NOTE: not sure the part below here is necessary. Maybe just link to web page documentation? If it is done, that is..

It can be useful to install the module to a separate environment. We have made this possible through `conda`,

```
conda environment create -f environment.yml
conda activate quantum-systems
```

6.1 Quantum Dots

In reality, quantum dots are nanometre-sized structures made of semiconductor materials. Theoretically, quantum dots are easy to model by harmonic oscillator potential and in practice they are relatively easy to manufacture in a laboratory. This doubly theoretical-experimental benefit has made quantum dots a popular area of study. Moreover so because of their wide area of applications.

The possible applications of quantum dots are many. Coupled single-electron quantum dots could potentially be used as hardware elements in quantum computers, i.e. qubits[38]; quantum dots also promise to increase the efficiency of photovoltaic solar cells; and they have already found use in cellular imaging in biology. Reimann and Manninen[49] has written an outstandingly thorough review on quantum dots, covering their varied types of fabrication, theoretical methods common in their study and vast ocean of applications.

The usefulness and relative theoretical ease of modelling warrants the study of quantum dots. Herein, several classes have been implemented in order to construct basis sets modelling quantum dots in both one and two dimensions. These basis sets models *bound* systems as the common harmonic oscillator-type potentials that are used have the characteristics of infinite quantum wells.

6.1.1 One Dimension

This is perhaps one of the simplest of all quantum mechanical models, being studied ad nauseum in everyones introductory quantum mechanics course. The one-body part of the Hamiltonian for the one-dimensional quantum harmonic oscillator is,

$$\hat{h} = \frac{\hat{p}^2}{2m} + \frac{1}{2}m\omega^2\hat{x}^2. \quad (6.1)$$

The potential, $\hat{v} = \frac{1}{2}m\omega^2\hat{x}^2$, forms the well known parabolig curve. In a general one-dimensional system, this potention could readily be exchanged for something else. For instance that of the *double well*,

$$\hat{v} = \frac{1}{2}m\omega^2 \left(\hat{x}^2 + \frac{1}{4}l^2 - l|\hat{x}| \right), \quad (6.2)$$

where l is the width of a barrier in the middle of the parabolic potential.

In atomic units we can set $\hbar = m = 1$. Substituting for the momentum operator, $\hat{p} = -i\hbar(\partial/\partial x)$, gives us

$$\hat{h} = -\frac{1}{2} \frac{\partial^2}{\partial x^2} + \hat{v}. \quad (6.3)$$

The second-order derivate can be approximated by the central difference formula for some function $f(x)$, yielding

$$f''(x) = \frac{f(x+dx) - 2f(x) + f(x-dx)}{dx^2}, \quad (6.4)$$

for some small dx . This means that we approximate the Hamilton operator of the system (Equation 6.3) by a matrix,

$$h_q^p = \begin{pmatrix} 1/dx^2 + v_1 & -1/2dx^2 & & \ddots & & \\ -1/2dx^2 & 1/dx^2 + v_2 & -1/2dx^2 & & \ddots & \\ & \ddots & -1/2dx^2 & 1/dx^2 + v_3 & -1/2dx^2 & \ddots \\ & & \ddots & \ddots & \ddots & \ddots \\ & & & \ddots & -1/2dx^2 & 1/dx^2 + v_{n-1} & -1/2dx^2 \\ & & & & \ddots & -1/2dx^2 & 1/dx^2 + v_n \end{pmatrix}, \quad (6.5)$$

and we have thus transformed the time-independent Schrödinger equation

$$\hat{h} |n\rangle = \epsilon |n\rangle, \quad (6.6)$$

into a matrix equation which is easily representable and solvable on a computer, where n is the number of points used to numerically represent the wavefunction and Hamiltonian matrix representation. This is done with some generic eigenvalue solver, for instance `numpy.linalg.eigh`. The eigen functions provide the foundations for the single-particle functions.

Since we would like to model interaction between particles we need something more, than just a numerical representation of the one-body operator. We therefore need to compute coulomb interaction, in the form of an integral. This is done in several steps, starting with an “inner integral” over all all space and two and two single-particle functions,

$$u_s^q = \int \phi_q(x_1) \frac{\alpha}{(x_1 - x_2)^2 + 2a^2} \phi_s(x_2) dx, \quad (6.7)$$

where a and α are parameters that are necessary to include for this integral to be calculable. Numerically, this part is divided into two functions in our python implementation,

```
def _shielded_coulomb(x_1, x_2, alpha, a):
    return alpha / np.sqrt((x_1 - x_2) ** 2 + a ** 2)

def _compute_inner_integral(spf, l, num_grid_points, grid, alpha, a):
    inner_integral = np.zeros((l, l, num_grid_points), dtype=np.complex128)

    for q in range(l):
        for s in range(l):
            for i in range(num_grid_points):
                inner_integral[q, s, i] = _trapz(
                    spf[q]
                    * _shielded_coulomb(grid[i], grid, alpha, a)
                    * spf[s],
                    grid,
                )

    return inner_integral
```

The inner orbital is then used in the computation in the orbital integral,

$$w_{rs}^{pq} = \int \phi_p u_s^q \phi_r dx, \quad (6.8)$$

which numerically is implemented as follows,

```
def _compute_orbital_integrals(spf, l, inner_integral, grid):
    u = np.zeros((l, l, l, l), dtype=np.complex128)

    for p in range(l):
        for q in range(l):
            for r in range(l):
                for s in range(l):
                    u[p, q, r, s] = _trapz(
                        spf[p] * inner_integral[q, s] * spf[r], grid
                    )

    return u
```

Each integral is solved by the trapezoidal scheme,

```
def _trapz(f, x):
    n = len(x)
    delta_x = x[1] - x[0]
    val = 0

    for i in range(1, n):
        val += f[i - 1] + f[i]

    return 0.5 * val * delta_x
```

Needless to say, computing the coulomb integrals is one of the more compute-heave tasks, and we therefore make great use of just-in-time compilation from the `numba` module for python. A full representation of the one-dimensional quantum dot (oscillator) class is provided below,

```
class quantum_systems.OneDimensionalHarmonicOscillator
    (n, l, grid_length, num_grid_points, omega=0.25, mass=1, a=0.25, alpha=1.0)
```

Create One-Dimensional Quantum Dot basis set.

Parameters

- n**(int) Number of electrons
- l**(int) Number of spinorbitals
- grid_length**(int or float) Space over which to construct wavefunction.
- num_grid_points**(int or float) Number of points for construction of wavefunction.
- omega**(float, default 0.25) Angular frequency of harmonic oscillator potential.
- mass**(int or float, default 1.0) Mass of electrons. Atomic units is used as default.
- a**(float, default 0.25) Necessary in Coulomb integral computation.
- alpha**(float, default 1.0) Necessary in Coulomb integral computation.

Attributes

- h** One-body matrix **Type** np.array
- f** Fock matrix **Type** np.array
- u** Two-body matrix **Type** np.array

Methods

- setup_system**(Potential=None)
Must be called in order to compute basis functions. The method will revert to regular harmonic oscillator potential if no potential has been provided. Optional potentials include one-dimensional double well potentials.
- construct_dipole_moment**()
Constructs dipole moment. This method is called by **setup_system**(). Necessary when constructing custom systems with time development.

6.1.2 Two Dimensions

The one-body part of the Hamiltonian for a two-dimensional quantum dots is almost identical to the one-body part for a one-dimensional quantum dot. In cartesian coordinates we simply include a y in the potential as well as an x , but mostly because we have analytical expressions for the Coulomb integrals in polar coordinates[2], we write the one-body operators in polar

coordinates as well with $\hat{r}^2 = \hat{x}^2 + \hat{y}^2$,

$$\hat{h} = \frac{\hat{p}^2}{2m} + \frac{1}{2}m\omega^2\hat{r}^2 = -\frac{\hbar^2}{2m} \left(\frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \frac{\partial^2}{\partial \theta^2} \right) + \frac{1}{2}m\omega^2\hat{r}^2. \quad (6.9)$$

The wavefunctions for a two-dimensional harmonic oscillator can be written

$$\phi(r, \theta) = N_{nm} R_{nm}(r) Y_m(\theta) = N_{nm} (ar)^{|m|} L_n^{|m|}(a^2 r^2) e^{-a^2 r^2/2} e^{im\theta}, \quad (6.10)$$

where $a = \sqrt{m\omega/\hbar}$ is the Bohr radius, $L_n^{|m|}$ is the associated Laguerre polynomials, n and m are the principal and the azimuthal quantum numbers respectively¹, and N_{nm} is a normalisation factor given by,

$$N_{nm} = a \sqrt{\frac{n!}{\pi(n+|m|)!}}. \quad (6.11)$$

The energy eigenvalues of a two-dimensional harmonic oscillator is given by

$$\epsilon_{nm} = \hbar\omega(2n + |m| + 1). \quad (6.12)$$

It is very beneficial that such a nice expression exists, because the one-body matrix elements of a harmonic oscillator is simply,

$$\langle \phi_p | \hat{h} | \phi_q \rangle = \hat{h}_q^p = \epsilon_p \delta_q^p. \quad (6.13)$$

These matrix elements encompass both the kinetic energy operator matrix element and potential energy matrix element. If we were dealing with completely none-interacting particles not much more would be needed. We see, however, that this form of one-body matrix elements necessitates a mapping from the general coordinates p, q , as used above, and the quantum numbers n, m .

This functionality $(n, m) \mapsto p$ is achieved by the following python function

```
def get_index_p(n, m):
    num_shells = 2 * n + abs(m) + 1

    previous_shell = 0
    for i in range(1, num_shells):
        previous_shell += i

    current_shell = previous_shell + num_shells

    if m == 0:
        if n == 0:
            return 0

    p = previous_shell + (current_shell - previous_shell) // 2

    return p

elif m < 0:
    return previous_shell + n
```

¹There is usually another quantum number called the magnetic quantum number. Because of our restriction to two dimensions, this quantum number does not appear. In three dimensions we would usually denote the azimuthal quantum number by l and the magnetic quantum number by m or m_l . A fourth quantum number is the spin projection quantum number commonly written m_s .

```

else:
    return current_shell - (n + 1)

```

It will also be necessary to map back $p \mapsto (n, m)$,

```

def get_indices_nm(p):
    n, m = 0, 0
    previous_shell = 0
    current_shell = 1
    shell_counter = 1

    while current_shell <= p:
        shell_counter += 1
        previous_shell = current_shell
        current_shell = previous_shell + shell_counter

    middle = (current_shell - previous_shell) / 2 + previous_shell

    if (current_shell - previous_shell) & 0x1 == 1 and abs(
        p - math.floor(middle)
    ) < 1e-8:
        n = shell_counter // 2
        m = 0

        return n, m

    if p < middle:
        n = p - previous_shell
        m = -((shell_counter - 1) - 2 * n)

    else:
        n = (current_shell - 1) - p
        m = (shell_counter - 1) - 2 * n

    return n, m

```

An important difference between the one-dimensional quantum dot and a two-dimensional quantum dot is that in the latter we have energy degeneracies of the eigenstates. This is illustrated in Figure 6.1. In this figure we have included a spin-up and a spin-down state for each n, m -state. This spin feature is not in any way included in Equation 6.10, but we may represent the spin condition by including it in the orthonormality conditions of the wavefunctions,

$$\langle n_1 m_1 \sigma_1 | n_2 m_2 \sigma_2 \rangle = \delta_{n_1 n_2} \delta_{m_1 m_2} \delta_{\sigma_1 \sigma_2}, \quad (6.14)$$

where σ is the spin.

Because the electrons we will be studying are interacting, we need two-body matrix elements as well. The analytical formula for the Coulomb interaction integrals, provided by Anisimovas

Abbildung 6.1: The lowest three energy levels in the two-dimensional quantum dot. Each arrow represents a spin up or a spin down state with the quantum numbers n and m as listed below. This pattern goes on indefinitely with the addition of one bar (two oscillators) per level.

and Matulis[2] is

$$\begin{aligned}
 \langle \phi_1 \phi_2 | \hat{W} | \phi_3 \phi_4 \rangle &= \delta_{s_1, s_4} \delta_{s_2, s_3} \delta_{m_1 + m_2, m_3 + m_4} \left[\prod_{i=1}^4 \frac{n_i!}{(|m_i| + n_i)} \right]^{1/2} \sum_{(4)j=0}^n \frac{(-1)^{j_1 + j_2 + j_3 + j_4}}{j_1! j_2! j_3! j_4!} \\
 &\times \left[\prod_{i=1}^n \binom{n_i + |m_i|}{n_i + j_i} \right] \frac{1}{2^{(G+1)/2}} \sum_{(4)l=0}^{\gamma} (-1)^{\gamma_2 + \gamma_3 - l_2 - l_3} \\
 &\times \delta_{l_1 + l_2, l_3 + l_4} \left[\prod_{i=1}^4 \binom{\gamma_i}{l_i} \right] \Gamma\left(1 + \frac{L}{2}\right) \Gamma\left(\frac{G - L + 1}{2}\right).
 \end{aligned} \tag{6.15}$$

The symbols j_i are integer summation indices (regular indices) running from 0 to n_i . The symbols γ_i stand for numbers,

$$\begin{aligned}
 \gamma_1 &= j_1 + j_4 + (|m_1| + m_1)/2 + (|m_4| - m_4)/2 \\
 \gamma_4 &= j_1 + j_4 + (|m_1| - m_1)/2 + (|m_4| + m_4)/2
 \end{aligned}$$

γ_2 and γ_3 can be obtained by replacing indices $1 \rightarrow 2$ and $4 \rightarrow 3$. Moreover,

$$\sum_{(4)j=0}^n = \sum_{j_1=0}^{n_1} \sum_{j_2=0}^{n_2} \sum_{j_3=0}^{n_3} \sum_{j_4=0}^{n_4}, \quad G = \sum_i \gamma_i, \quad L = \sum_i l_i$$

For the implementation of this expression for the purpose of computing the two-dimensional quantum dot basis sets, we refer the reader to the appendices (Appendix C).

Dipole Moments For our implementation of time dependent Hamiltonians, outlined below, we make use of a dipole approximation of an electric field. For this reason it is necessary to compute dipole moments. Moreover, the “transitions rules” of quantum mechanics stems from evaluating matrix elements of this kind,

$$\mathbf{d}_{pq} = \langle \phi_p | \hat{\mathbf{r}} | \phi_q \rangle = \hat{i} \langle \phi_p | \hat{x} | \phi_q \rangle + \hat{j} \langle \phi_p | \hat{y} | \phi_q \rangle, \tag{6.16}$$

where ϕ_p, ϕ_q are some typical state vectors, on the form in Equation 6.10. As we will be representing the two-dimensional quantum dots in polar coordinates, we can rewrite this to,

$$\mathbf{d}_{pq} = \hat{i} \langle \phi_p | \hat{r} \cos \hat{\theta} | \phi_q \rangle = \hat{j} \langle \phi_p | \hat{r} \sin \hat{\theta} | \phi_q \rangle. \tag{6.17}$$

The integrals we need to compute are

$$\langle \phi_p | r \cos \theta | \phi_q \rangle = N_{nm}^* N_{nm} \int_0^\infty r^2 R_{nm}^*(r) R_{nm}(r) dr \int_0^{2\pi} \cos \theta Y_m^*(\theta) Y_m(\theta) d\theta \tag{6.18}$$

$$\langle \phi_p | r \sin \theta | \phi_q \rangle = N_{nm}^* N_{nm} \int_0^\infty r^2 R_{nm}^*(r) R_{nm}(r) dr \int_0^{2\pi} \sin \theta Y_m^*(\theta) Y_m(\theta) d\theta. \quad (6.19)$$

The radially dependent integrals are the most difficult to compute, and we compute this symbolically with `sympy`. For the angular integrals, we can find analytical expressions that can be evaluated quickly,

$$\int_0^{2\pi} \cos \theta e^{i\bar{m}\theta} d\theta = \frac{e^{i\bar{m}\theta}}{1 - \bar{m}^2} (\sin \theta - i\bar{m} \cos \theta) \Big|_0^{2\pi}, \quad (6.20)$$

where $\bar{m} = (m_q - m_p) \in \mathbb{Z}$. We see that the integral evaluates to 0 for all possible values of \bar{m} except for ± 1 . This special case warrants further investigation,

$$\int_0^{2\pi} \cos \theta e^{i\theta} d\theta = \int_0^{2\pi} \cos^2 \theta + i \cos \theta \sin \theta d\theta = \frac{1}{2} \sin \theta \cos \theta + \frac{\theta}{2} + \frac{i}{2} \sin^2 \theta \Big|_0^{2\pi} = \pi. \quad (6.21)$$

Similarly,

$$\begin{aligned} \int_0^{2\pi} \sin \theta e^{i\bar{m}\theta} d\theta &= \frac{e^{i\bar{m}\theta}}{1 - \bar{m}^2} (i\bar{m} \sin \theta - \cos \theta) \Big|_0^{2\pi} = 0 \quad \forall \bar{m} \in \mathbb{Z} \neq 1 \\ \int_0^{2\pi} \sin \theta e^{i\theta} d\theta &= \int_0^{2\pi} \cos \theta \sin \theta + i \sin^2 \theta d\theta = \frac{1}{2} \sin \theta - \frac{i}{2} \sin \theta \cos \theta + i \frac{\theta}{2} \Big|_0^{2\pi} = i\pi \end{aligned} \quad (6.22)$$

This is a very nice result, as it conforms with the selection rule related to the azimuthal quantum number m .

The final specification of the two-dimensional harmonic oscillator basis set class, which is everything the user sees is the following,

```
class quantum_systems.TwoDimensionalHarmonicOscillator
    (n, l, radius_length, num_grid_points, omega=0.25, mass=1)
```

Create Two-Dimensional Quantum Dot basis set.

Parameters

n(int) Number of electrons
l(int) Number of spinorbitals
grid_length(int or float) Space over which to construct wavefunction.
num_grid_points(int or float) Number of points for construction of wavefunction.
omega(float, default 0.25) Angular frequency of harmonic oscillator potential.
mass(int or float, default 1.0) Mass of electrons. Atomic units is used as default.

Attributes

h One-body matrix **Type** np.array
f Fock matrix **Type** np.array
u Two-body matrix **Type** np.array

Methods

setup_system()
 Must be called in order to compute basis functions.
construct_dipole_moment()
 Constructs dipole moment. This method is called by **setup_system()**.

Double well

The extension from a single two-dimensional quantum dot to a double quantum dot is a relatively straight-forward procedure, as it is a mere perturbation of the regular single dot. What is more, the double dot system has more possible energy transitions and it has more energy degeneracies, making it a more interesting system to study. There are several ways to define the double quantum dot. We have devised two different potentials that accomplish the task. The first is with a sharp edge and the other with a smoother bulge dividing the two potential wells.

Starting with the sharp-edge implementation the one-body operators is as follows,

$$\hat{h} = \frac{\hat{p}^2}{2m} + \frac{1}{2}m\omega^2\hat{r}^2 + \frac{1}{2}\left(\frac{1}{4}l^2 - l|\hat{x}|\right), \quad (6.23)$$

where l is the “strength” of the barrier between the wells. We can readily see what makes the barrier so acute, namely the absolute value of the position operator, $|\hat{x}|^2$.

In Equation 6.23, we immediately recognise the first two terms as the normal quantum dot. This is beneficial, as we can reuse single-particle functions from Equation 6.10. This means that the one-body matrix elements are simply,

$$\begin{aligned} h_q^p &= \epsilon_p \delta_q^p + \frac{1}{2}m\omega^2 \langle \phi_p | \frac{1}{4}l^2 - l|\hat{x}| | \phi_q \rangle \\ &= \epsilon_p \delta_q^p + \frac{1}{8}m\omega^2 l^2 \delta_q^p - \frac{1}{2}m\omega^2 l \langle \phi_p | |\hat{x}| | \phi_q \rangle. \end{aligned} \quad (6.24)$$

We see from the first two terms a perturbation in the diagonal matrix elements, i.e.

$$\epsilon_p^{\text{DW}} = \epsilon_p + \frac{1}{8}m\omega^2 l^2, \quad (6.25)$$

and that we need only compute the matrix elements of the position operator. Because we are still working with polar coordinates, we make the necessary transformation, and the integral becomes

$$\langle \phi_p | |\hat{x}| | \phi_q \rangle = \int_0^\infty \int_0^{2\pi} \phi_{n_p m_p}^*(r, \theta) r^2 |\cos \theta| \phi_{n_q m_q}(r, \theta) dr d\theta \quad (6.26)$$

We see that the wavefunctions $\phi_{n,m}$ are the same as for the unperturbed two-dimensional quantum dot, and this directs us to the same kind of integrals as for the dipole calculations above. The radial integral is cumbersome, and therefore left for a symbolic solver, but for angular integral we can at least give the computer some help,

$$\int_0^{2\pi} |\cos \theta| e^{i\bar{m}\theta} d\theta = \frac{i(1 + e^{i\pi n})(\bar{m} + 2ie^{(i\pi\bar{m}/2)} - \bar{m}e^{i\pi n})}{\bar{m}^2 - 1}, \quad (6.27)$$

where $\bar{m} = (m_q - m_p) \in \mathbb{Z}$. We see that this expression is not defined for $\bar{m} = 1$, but inserting for this value in the integral will yield zero as a result. In fact, the integral will evaluate to zero for each odd value of \bar{m} . If the barrier was aligned in the other direction, along the y -axis, a similar computation can be performed for \sin instead of \cos .

Since the particles are interacting in the same way as before, there is no need to compute a special version of the Coulomb integral matrix elements for the double well. We do, however, need to transform the single-particle functions and two-body elements from the regular harmonic oscillator basis to an approximate basis for the double-well problem. This can be done via diagonalisation of the one-body Hamiltonian in order to find a matrix of coefficients \mathbf{C} , that perform this basis change,

$$|\phi_q\rangle_{\text{DW}} = \sum_p C_p |\phi_p\rangle_{\text{HO}}, \quad (6.28)$$

²Here we might as well have used the position operator \hat{y} , which would have resulted in an equivalent potential, rotated ninety degrees.

which can be inserted into an eigenvalue equation for the one-body operator,

$$\begin{aligned}\hat{h}|\psi_q\rangle_{\text{DW}} &= \epsilon_q |\psi_q\rangle_{\text{DW}} \\ \sum_p \hat{h}C_p |\phi_p\rangle &= \sum_p \epsilon_p C_{pq} |\phi_p\rangle.\end{aligned}\quad (6.29)$$

Assuming that the eigenvalues ϵ_q are eigenvalues for the double well single-particle functions, we project onto the regular harmonic oscillator basis,

$$\begin{aligned}\sum_p \langle\phi_r|\hat{h}|\phi_p\rangle &= \sum_p C_{pr}\epsilon_p \langle\phi_r|\phi_p\rangle \\ \sum_p h_{pr}C_{pr} &= C_{pr}\epsilon_p \\ \mathbf{hC} &= \mathbf{C}\epsilon\end{aligned}\quad (6.30)$$

This is an eigenvalue equation we can solve in order to obtain the coefficient matrix which transforms from the one basis to the other. This transformation can subsequently be applied to the two-body operator,

$$\langle\psi_\alpha\psi_\beta|\hat{w}|\psi_\gamma\psi_\delta\rangle = C_\alpha^{p*}C_\beta^{p*}\langle\phi_p\phi_q|\hat{w}|\phi_r\phi_s\rangle C_\gamma^r C_\delta^s, \quad (6.31)$$

where summation over same indices is assumed.

class quantum_systems.**TwoDimensionalDoubleWell**

(*n*, *l*, *radius_length*, *num_grid_points*, *barrier_strength*=1.0, *l_ho_factor*=1.0, *omega*=0.25, *mass*=1)

Create Two-Dimensional Quantum Dot with double well potential, i.e. the Double Dot. This class inherits from **TwoDimensionalHarmonicOscillator**.

Parameters

n(*int*) Number of electrons
l(*int*) Number of spinorbitals
grid_length(*int or float*) Space over which to construct wavefunction.
num_grid_points(*int or float*) Number of points for construction of wavefunction.
barrier_strength(*float, default 1.0*) Barrier strength in double well potential.
l_ho_factor(*float, default 1.0*) Normal HO vs double well basis function multiple.
omega(*float, default 0.25*) Angular frequency of harmonic oscillator potential.
mass(*int or float, default 1.0*) Mass of electrons. Atomic units is used as default.

Attributes

h One-body matrix **Type** np.array
f Fock matrix **Type** np.array
u Two-body matrix **Type** np.array

Methods

setup_system(*axis*=0)
 Must be called in order to compute basis functions. Parameter *axis* decides to which axis the well barrier is aligned. (0,1) = (*x*,*y*).

HERE COMES THE SMOOTH *potential double*.

Abbildung 6.2: A few of the lowest eigenvalues ϵ_{nm} for a two-dimensional quantum dot for transverse magnetic field of increasing strength. This plot of the single-particle energies form the Fock-Darwin spectrum. Some states for very high values of m are omitted to make the formation of Landau bands in strong fields more visible.

Magnetic field

Extending the two-dimensional quantum dot to be under the influence of a static, transverse magnetic field is relatively effortless. We are considering a system with the following one-body hamiltonian,

$$\hat{h} = \frac{\hat{p}^2}{2m} + \frac{1}{2}m\Omega^2\hat{r}^2 + \frac{\omega_c}{2}\hat{L}_z, \quad (6.32)$$

where $\Omega = \sqrt{\omega_0^2 + \frac{\omega_c^2}{4}}$ and ω_c is the parameter dictating the strength of the magnetic field. We see that this Hamiltonian is the same as the normal two-dimensional quantum dot one-body Hamiltonian (Equation 6.9) for $\omega_c = 0$ as $\Omega \rightarrow \omega_0$, which is the well potential frequency. Conversely, if the magnetic field is infinitely strong we see that $\Omega \rightarrow \omega_c/2$ and Equation 6.32 becomes the one-body hamiltonian of a free electron in a transverse magnetic field. The single-particle functions (Equation 6.10) with the adjusted Bohr radius $a = \sqrt{m\Omega/\hbar}$, are also eigenfunctions of the angular momentum L_z and the energy eigenvalues are simply

$$\epsilon_{nm} = \hbar\Omega(2n + |m| + 1) - \frac{\hbar\omega_c}{2}m. \quad (6.33)$$

We see immediately that the energy undergoes a general shift due to the new Ω which is dependent on ω_c , but also that the energy shift of a particular shift is dependent on the sign of the azimuthal quantum number m for the given state. These factors will give different degeneracies, as illustrated in Figure 6.2. Such a plot of single-particle particle energies are sometimes referred to as the Fock-Darwin spectrum[17, 11]. With this comes the challenge of sorting the one-body matrix elements correctly, and ensuring that the closed-shell structure.

Notice in Figure 6.2, that there are lengthy intervals of b-field strength where there is no degeneracy in the eigenenergies. Conversely, there for certain specific field strengths there are very interesting shell structures with diverse energies. For $\omega_c/\omega = 1/\sqrt{2}$ we get the

Abbildung 6.3: Illustration of eigenenergy degeneracies for two-dimensional quantum dot for transverse magnetic field of strength $\omega_c = 1/\sqrt{2}$. Each dot

interesting shell structure depicted in Figure 6.3. Such accidental bunching also occurs for $\omega_c/\omega = 2/\sqrt{3}, 3/2, 4/\sqrt{5} \dots$. We also see from figure Figure 6.2 that for an infinitely strong magnetic field as $\omega_c/\omega \rightarrow \infty$, in the free particle limit, that the energy levels form a sequence of so-called Landau bands.

As for the computation of the basis set, not much needs to be added in the computation than the extra energy to the diagonal part of the one-body matrix elements h_q^p , as everything else is the same, including the two-body Coulomb integrals. But, as we have already mentioned and displayed in Figure 6.2, for increasing strength of the magnetic field, the eigenenergies as function of ω_c eventually cross over one another. The magnetic field has the effect of decreasing the energy of a state with $m > 0$ and increasing the energy of a state with $m < 0$. This means that it is necessary to sort the eigenvalues after they have been computed.

The class specification of the two-dimensional quantum dot subjected to a transverse, homogeneous, static magnetic field is below.

```
class quantum_systems.TwoDimHarmonicOscB
```

```
(n, l, radius_length, num_grid_points, omega_0=1.0, mass=1, omega_c=0)
```

Create Two-Dimensional Quantum Dot with constant homogenous magnetic field. This class inherits from **TwoDimensionalHarmonicOscillator**.

Parameters

n(*int*) Number of electrons

l(*int*) Number of spinorbitals

grid_length(*int or float*) Space over which to construct wavefunction.

num_grid_points(*int or float*) Number of points for construction of wavefunction.

omega_0(*float, default 1.0*) Part of harmonic osc. not dep. on magnetic field.

mass(*int or float, default 1.0*) Mass of electrons. Atomic units is used as default.

omega_c(*float, default 0*) Frequency corresponding to strenght of magnetic field.

Attributes

h One-body matrix **Type** np.array

f Fock matrix **Type** np.array

u Two-body matrix **Type** np.array

Methods

setup_system()

Must be called in order to compute basis functions.

construct_dipole_moment()

Constructs dipole moment. This method is called by `setup_system()`.

6.3 Time Evolution

Kapitel 7

Benchmarks

7.1 Zanghellini

Zanghellini et al.[59] calculate the time development of a one-dimensional quantum dot with two electrons using the multi-configurational time-dependent Hartree-Fock method (MCTDHF). This method yields exact results for a very large number of configurations, $\eta \rightarrow \infty$. This study would provide a proper benchmark for our implementation because the coupled cluster method with singles and doubles excitations (CCSD) is exact for $n = 2$ particles. The harmonic oscillator potential applied in their study had a frequency of $\omega = 0.25$, used a strong laser-like field with maximum intensity of $E = 1$ and a laser frequency of $\Omega = 8\omega = 2$. Their MCTDHF scheme converges with $\eta = 15$ configurations up to the resolution of their figures. We are able to reproduce their results precisely by employing the time-dependent coupled cluster method with singles and double excitations (TDCCSD) with static orbitals, using $l = 20$ spin-orbitals in the basis set.

In Figure 7.1 we see the ground state electron density for the ground state wavefunction computed with CCSD. Zanghellini et al. computed the electron density for an increasing number of configurations η using multi-configurational Hartree-Fock (MCHF). This figure matches the convergent electron density found by Zanghellini et al. as $\eta \rightarrow \infty$, in figure 1 from their article.

Figure 7.2 depicts the probability for the system being in the ground state as a function of time. Here we have included both a time-dependent Hartree-Fock computation, corresponding to a MCTDHF computation with $\eta = 1$ configurations, and a TDCCSD computation, corresponding to MCTDHF when $\eta \rightarrow \infty$. We find that our plots match Zanghellini et al.'s plots in their figure 2 precisely.

Abbildung 7.1: Electron density for the ground state wavefunction of a quantum dot with $n = 2$ electrons and $l = 20$ spin-orbitals in the basis set computed with CCSD. This plot corresponds precisely with figure 1 in Zanghellini et al.[59].

Abbildung 7.2: Probability of being in the ground state $|\langle\Phi(0)|\Phi(t)\rangle|$ using both TDHF and TDCCSD, for a one-dimensional quantum dot with $n = 2$ particles and $l = 20$ spin-orbitals. This plot corresponds precisely with figure 2 in Zanghellini et al.[59].

Kapitel 8

Magnetic Fields

We start the study of two-dimensional quantum dots under the influence of a magnetic field by defining a system of only one particle and solving the time-dependent Schrödinger equation directly. This is accomplished by using the `TwoDimHarmonicOscB` class to produce a basis set, single-particle functions and transition/interaction matrix (dipole elements), which is everything we need. All of these items are properties of the class and can be easily extracted. A simple periodic function simulating an electric field is constructed, as the product of such a time-dependent operator and the interaction matrix defines the time propagation. We then use a simple integration scheme, in this case the fourth-order Runge-Kutta method, to propagate the ground state single particle function of the system. Taking care to extract the dipole for every time step, we can compute the discrete Fourier transform of the dipole and compute the frequency spectrum of our system. This procedure is applied to a system completely absent of a magnetic field, and a system under direct influence of a magnetic field.

Before going straight to the results, we study the shell structure and allowed transitions of our two systems. The left part of Figure 8.1 presents the shell structure of a regular two-dimensional quantum dot. The states have all been assigned a number for easier examination. This shell structure is identical to the one presented in Figure 6.1. Additionally, here we have added coloured double arrows to illustrate the allowed transitions in the quantum dot. These transitions can be encountered in the transition matrix for the system, which is reproduced in the artistic way in Figure 8.2. Notice that the coloured arrows representing allowed transitions match in colour with the elements of the transition matrix.

When we apply a magnetic field of strength $\omega_c/\omega = \sqrt{2}/2$ we obtain the shell struc-

Abbildung 8.1: Shell structure of six lowest orbitals before (left), and after (right) a magnetic field is applied to a 2D quantum dot.

Abbildung 8.2: Transition matrix dictating the allowed transitions for a 2D quantum dot. Abbildung 8.3: transition matrix for a 2D quantum dot when a magnetic field is applied.

ture represented to the right in Figure 8.1, where the allowed transitions correspond to the transition matrix in Figure 8.3. The chosen magnetic field strength was not chosen arbitrarily, as these accidental degeneracies occur only rarely as a function of magnetic field strength¹. For succinctness we repeat the function for energy eigenvalues for two-dimensional quantum dot influenced by a magnetic field (Equation 6.33),

$$\epsilon_{nm} = \hbar\Omega(2n + |m| + 1) - \frac{\hbar\omega_c}{2}m, \quad (8.1)$$

where $\Omega = \sqrt{\omega_0^2 + \frac{\omega_c^2}{4}}$. Apart from a general shift up in energy by adding a magnetic field, the states with negative azimuthal quantum number m will experience an increase in energy eigenvalue, and vice versa. We see this effect clearly in the new shell structure in Figure 8.1. The states with negative m have indeed undergone a relative shift upwards, whilst the states with positive m have been shifted downwards, relative to the other states. The ground state, labelled 0, remains relatively stationary, the states labelled 2 ($m = 1$) and 4 ($m = 2$) have been shifted downwards and the states labelled 1 ($m = -1$) and 5 ($m = -2$) have been shifted upwards. State number 5 so much that it has disappeared from the shell structure, with a new state 6 ($= 3$) appearing. This is due to our restriction to include only the six lowest-energy orbitals. We see that the possible remaining allowed transitions remain the same, with the exception of transitioning between state 1 and 5, because state 5 is no more, and the addition of a possible transition between state 4 and 6.

If we compute the frequency spectrum of the two systems (Figure 8.4) we get a single line for the normal quantum dot. This is expected, as the quantum harmonic oscillator has the same energy difference between each level. However, when we apply a magnetic field and shift the energies of the orbitals in the quantum dot, we see that we get two different energy transitions. This is revealed as two lines in the frequency spectrum in Figure 8.4. This is equivalent to a splitting in transmission spectra of quantum dot arrays under the effect of a magnetic field in experiments[25, 39].

¹Hence the term “accidental”.

Abbildung 8.4: Spectrum of a 2D quantum dot both with and without a magnetic field.

Anhang A

Slater-Condon Rules

The Slater-Condon rules are ways to express integrals over operators in terms of single-particle orbitals. Here is an outline of a proof for these rules.

Consider first some Slater determinants,

$$|I\rangle = |i_1 i_2 \dots i_N\rangle = \hat{i}_1^\dagger \hat{i}_2^\dagger \dots \hat{i}_N^\dagger | \rangle \quad (\text{A.1})$$

$$|J\rangle = |j_1 j_2 \dots j_N\rangle = \hat{j}_1^\dagger \hat{j}_2^\dagger \dots \hat{j}_N^\dagger | \rangle. \quad (\text{A.2})$$

To get started, we want to compute the inner product $\langle I|J\rangle$ of these two Slater determinants,

$$\langle I|J\rangle = \langle \hat{i}_N \dots \hat{i}_2 \hat{i}_1 \hat{j}_1^\dagger \hat{j}_2^\dagger \dots \hat{j}_N^\dagger | \rangle. \quad (\text{A.3})$$

In order to evaluate this expression, we move every annihilation operator \hat{i}_p to the right. Starting with \hat{i}_1 , for instance, we have two possible outcomes. If there is no \hat{j}_q that is the same as \hat{i}_1 we get

$$\langle I|J\rangle = \langle \hat{i}_N \dots \hat{i}_2 \hat{j}_1^\dagger \hat{j}_2^\dagger \dots \hat{j}_N^\dagger \hat{i}_1 | \rangle (-1)^N = 0, \quad (\text{A.4})$$

because $\hat{i}_1 | \rangle = 0$. The other possibility that may arise is that $\hat{i}_1 = \hat{j}_q$, so that

$$\hat{i}_1 \hat{j}_q^\dagger = \{\hat{i}_1, \hat{j}_q^\dagger\} - \hat{j}_q^\dagger \hat{i}_1 = \delta_{i_1 k_q} - \hat{j}_p^\dagger \hat{i}_1 = \hat{1} - \hat{j}_q^\dagger \hat{i}_1, \quad (\text{A.5})$$

and

$$\langle I|J\rangle = \langle \hat{i}_N \dots \hat{i}_2 \hat{j}_1^\dagger \hat{j}_2^\dagger \dots \hat{j}_{p-1}^\dagger \hat{j}_{p+1}^\dagger \dots \hat{j}_N^\dagger \hat{i}_1 | \rangle (-1)^{p-1} - 0. \quad (\text{A.6})$$

We continue in this manner, moving all \hat{i} to the right and the final result will be zero if there are any \hat{i}_p without a matching \hat{j}_q or $(-1)^\tau$ if the two operator strings are identical to a permutation τ .

Next, consider a symmetric one-body operator

$$\hat{F} = \sum_{\mu=1}^N \hat{f}_\mu, \quad (\text{A.7})$$

where μ is the identity of the electron on which the identical \hat{f}_μ operate. Computing a matrix element of this one-body operator between two Slater determinants will yield three possible

results,

$$\begin{aligned}
\langle I | \hat{F} | J \rangle &= \langle i_1 i_2 \dots i_N | \hat{F} | j_1 j_2 \dots j_N \rangle \\
&= \sum_{\mu} \langle i_1 i_2 \dots i_N | \hat{f}_{\mu} | j_1 j_2 \dots j_N \rangle \\
&= \sum_{\mu} \langle \phi_{i_1} \phi_{i_2} \dots \phi_{i_N} | \hat{f}_{\mu} \sum_{\hat{P}} (-1)^{\sigma(\hat{P})} | \hat{P} \phi_{j_1} \phi_{j_2} \dots \phi_{j_N} \rangle = \begin{cases} \sum_k \langle i_k | \hat{f} | i_k \rangle (-1)^{\sigma(\hat{P})} & \text{I} \\ \langle i_k | \hat{f} | i'_k \rangle (-1)^{\sigma(\hat{P})} & \text{II} \\ 0 & \text{III} \end{cases} \quad (\text{A.8})
\end{aligned}$$

In the last line, the integral is written with spinorbitals instead of Slater determinants. The result will be the first case (I), if the operators needed to construct the Slater determinants are the same, up to a permutation with permutation parity σ associated with the permutation operator \hat{P} needed to permute the product of spinorbitals. If there exists exactly one noncoincidence in the string of operators so that $\hat{P} j_1 j_2 \dots j_N = i_1 i_2 \dots i'_k \dots i_N$ where $i_k \neq i'_k$, we get the result in the second case (II). If there are two or more noncoincidences, the result is zero (III).

With second quantisation we might write a one-electron operators differently,

$$\sum_{kl} \langle k | \hat{f} | l \rangle \hat{a}_k^{\dagger} \hat{a}_l = \sum_{kl} f_{kl} \hat{a}_k^{\dagger} \hat{a}_l. \quad (\text{A.9})$$

It is possible to show that the results are the same in this representation. First, consider the case where the two Slater determinants are equal,

$$\begin{aligned}
\langle I | \sum_{kl} f_{kl} \hat{a}_k^{\dagger} \hat{a}_l | I \rangle &= \sum_{kl} f_{kl} \langle I | \hat{a}_k^{\dagger} \hat{a}_l | I \rangle \\
&= \sum_{kl} f_{kl} \delta_{kl} n_l(I) = \sum_{k \in I} f_{kk} = \sum_{k=1}^N \langle i_k | \hat{f} | i_k \rangle. \quad (\text{A.10})
\end{aligned}$$

Second, we look at the case where we have one noncoincidence, $i_p \neq j_p$,

$$\begin{aligned}
\langle I | \sum_{kl} f_{kl} \langle I | \hat{a}_k^{\dagger} \hat{a}_l | J \rangle &= \sum_{kl} f_{kl} \langle I | \hat{a}_k^{\dagger} \hat{a}_l | J \rangle \\
&= \sum_{kl \neq p} f_{kl} \langle I | \hat{a}_k^{\dagger} \hat{a}_l | J \rangle + f_{i_p j_p} \langle I | \hat{a}_{i_p}^{\dagger} \hat{a}_{j_p} | J \rangle \\
&= 0 + f_{i_p j_p} \langle I' | I' \rangle = \langle \hat{i}_p | \hat{f} | \hat{i}_p \rangle. \quad (\text{A.11})
\end{aligned}$$

Lastly, there is no pair of operators $\hat{a}_k^{\dagger} \hat{a}_l$ that will give a non-zero result. Consequently, we see that the second-quantised form of the one-body operator gives the same result.

Similarly, consider a symmetric two-body operator,

$$\hat{G} = \sum_{\mu < \nu}^N \hat{g}_{\mu\nu} = \frac{1}{2} \sum_{\mu \neq \nu}^N \hat{g}_{\mu\nu} = \frac{1}{2} \sum_{ijkl} \langle ij | \hat{g} | kl \rangle \hat{a}_i^{\dagger} \hat{a}_j^{\dagger} \hat{a}_l \hat{a}_k. \quad (\text{A.12})$$

We would like to show that the second-quantized form is correct, and therefore firstly consider the case where the two Slater determinants are equal, i.e. zero noncoincidences;

$$\langle I | \hat{G} | I \rangle = \frac{1}{2} \sum_{ijkl} \langle ij | \hat{G} | kl \rangle \langle I | \hat{a}_i^{\dagger} \hat{a}_j^{\dagger} \hat{a}_l \hat{a}_k | I \rangle. \quad (\text{A.13})$$

We must have $k = i_p$ and $l = i_q$ appear in $|I\rangle$, so that

$$\begin{aligned}\langle I | \hat{G} | I \rangle &= \frac{1}{2} \sum_{ij} \langle ij | \hat{g} | i_p i_q \rangle \langle I | \hat{a}_i^\dagger \hat{a}_j^\dagger \hat{a}_{i_p} \hat{a}_{i_q} | i_1 i_2 \dots i_p \dots i_q \dots \rangle \\ &= \frac{1}{2} \sum_{ij} \langle ij | \hat{g} | i_p i_q \rangle \langle I | \hat{a}_i^\dagger \hat{a}_j^\dagger | i_1 i_2 \dots \rangle (-1)^{(p-1)+(q-2)}.\end{aligned}\quad (\text{A.14})$$

From this point we have two possibilities for the values of i and j , because the creation operators must put the same values back into the ket,

$$\begin{aligned}\langle i_p i_q | \hat{g} | i_p i_q \rangle \langle I | i_1 i_2 \dots i_p \dots i_q \dots \rangle (-1)^{(p-1)+(q-2)} (-1)^{(p-1)+(q-2)} \\ = \langle i_p i_q | \hat{g} | i_p i_q \rangle\end{aligned}\quad (i = i_p, j = i_q); \quad (\text{A.15})$$

$$\begin{aligned}\langle i_q i_p | \hat{g} | i_p i_q \rangle \langle I | i_1 i_2 \dots i_p \dots i_q \dots \rangle (-1)^{(p-1)+(q-2)} (-1)^{(p-1)+(q-1)} \\ = -\langle i_q i_p | \hat{g} | i_p i_q \rangle = -\langle i_p i_q | \hat{g} | i_q i_p \rangle\end{aligned}\quad (i = i_q, j = i_p). \quad (\text{A.16})$$

By starting in the reverse order, we obtain the same contributions. The total matrix element is therefore,

$$\langle I | \hat{G} | I \rangle = \frac{1}{2} \sum_{i \in I} \sum_{j \in J} (\langle ij | \hat{g} | ij \rangle - \langle ij | \hat{g} | ji \rangle) = \sum_{\substack{i < j \\ i, j \in I}} \langle ij | \hat{g} | ij \rangle_{\text{AS}}. \quad (\text{A.17})$$

Next, we consider a single noncoincidence in $|I\rangle$, $i_p \neq i'_p$,

$$|I\rangle = |i_1 i_2 \dots i_p \dots\rangle, \quad (\text{A.18})$$

$$|I'\rangle = |i_1 i_2 \dots i'_p \dots\rangle. \quad (\text{A.19})$$

We get contributions to $\langle I | \hat{G} | I' \rangle$ from the operator string $\hat{a}_i^\dagger \hat{a}_j^\dagger \hat{a}_l \hat{a}_k$ in the following cases,

$$i = i'_p, k = i_p, j = l = i_q \rightarrow \langle i'_p i_q | i_p i_q \rangle \quad (\text{A.20})$$

$$i = i'_p, l = i_p, j = k = i_q \rightarrow -\langle i'_p i_q | i_q i_p \rangle \quad (\text{A.21})$$

$$j = i'_p, l = i_p, i = k = i_q \rightarrow \langle i_q i'_p | i_q i_q \rangle \quad (\text{A.22})$$

$$j = i'_p, k = i_p, i = l = i_q \rightarrow -\langle i_q i'_p | i_p i_q \rangle, \quad (\text{A.23})$$

where the two first terms are equal to the last terms, respectively. This leaves us with,

$$\langle I' | \hat{G} | I \rangle = 2 \times \frac{1}{2} (\langle i'_p j | \hat{g} | i_p j \rangle - \langle i'_p j | \hat{g} | j i_p \rangle) = \sum_{j \in I} \langle i'_p j | \hat{g} | i_p j \rangle_{\text{AS}}. \quad (\text{A.24})$$

After a while we see a pattern emerges. For two noncoincidences ($i_p \neq i'_p, i_q \neq i'_q$) we have,

$$\langle I' | \hat{G} | I \rangle = \langle i'_p i'_q | \hat{g} | i_p i_q \rangle, \quad (\text{A.25})$$

while for three or more noncoincidences,

$$\langle I' | \hat{G} | I \rangle = 0. \quad (\text{A.26})$$

Anhang B

Diagrammatic Notation

B.1 Slater determinants

Drawing the reference state will result in a drawing of nothing. A single-excited reference state is two vertical arrows

$$\Phi_i^a = \begin{array}{c} | \\ \text{i} \uparrow \\ | \end{array} \begin{array}{c} | \\ \downarrow \text{a} \\ | \end{array} , \quad (\text{B.1})$$

while the double-excited Slater determinant consists of four vertical arrows,

$$\Phi_{ij}^{ab} = \begin{array}{c} | \\ \text{i} \uparrow \\ | \end{array} \begin{array}{c} | \\ \downarrow \text{a} \\ | \end{array} \begin{array}{c} | \\ \text{j} \uparrow \\ | \end{array} \begin{array}{c} | \\ \downarrow \text{b} \\ | \end{array} . \quad (\text{B.2})$$

The horizontal positions of the lines have no significance. If we want to indicate a bra or ket form we draw a couple of horizontal lines,

$$|\Phi_i^a\rangle = \{\hat{a}^\dagger \hat{i}\} |0\rangle = \begin{array}{c} | \\ \text{i} \uparrow \\ | \end{array} \begin{array}{c} | \\ \downarrow \text{a} \\ | \end{array} , \quad \langle \Phi_i^a| = \langle 0| \{\hat{i}^\dagger \hat{a}\} = \begin{array}{c} \overline{\overline{|}} \\ \text{i} \uparrow \\ | \end{array} \begin{array}{c} \overline{\overline{|}} \\ \downarrow \text{a} \\ | \end{array} , \quad (\text{B.3})$$

where $\{ABC \dots\}$ is a normal ordered product relative to the Fermi vacuum. A double-excited ket state could be drawn like

$$|\phi_{ij}^{ab}\rangle = \{\hat{a}^\dagger \hat{b}^\dagger \hat{j} \hat{i}\} |0\rangle = \{(\hat{a}^\dagger \hat{i})(\hat{b}^\dagger \hat{j})\} |0\rangle = \begin{array}{c} | \\ \text{i} \uparrow \\ | \end{array} \begin{array}{c} | \\ \downarrow \text{a} \\ | \end{array} \begin{array}{c} | \\ \text{j} \uparrow \\ | \end{array} \begin{array}{c} | \\ \downarrow \text{b} \\ | \end{array} \quad (\text{B.4})$$

This drawing could, however, also mean $|\phi_{ij}^{ba}\rangle$. The use of diagrams will be independent of this ambiguity, as long as one remains consistent. To be precise one can introduce dotted/dashed

lines,

$$|\phi_{ij}^{ab}\rangle = \{\hat{a}^\dagger \hat{b}^\dagger \hat{j} \hat{i}\} |0\rangle = \{(\hat{a}^\dagger \hat{i})(\hat{b}^\dagger \hat{j})\} |0\rangle = \begin{array}{c} \text{i} \uparrow \quad \text{a} \downarrow \quad \text{j} \uparrow \quad \text{b} \downarrow \\ \hline \text{---} \end{array} \quad (\text{B.5})$$

These indicate what index letters should be above and below one another.

B.2 One-Body Operator

The one-electron operator on normal-ordered form is given by

$$\hat{U}_N = \sum_{pq} \langle p | \hat{u} | q \rangle \{\hat{p}^\dagger \hat{q}\}, \quad (\text{B.6})$$

acting on a singly excited Slater determinant

$$|\Phi_i^a\rangle = \{\hat{a}^\dagger \hat{i}\} |0\rangle, \quad (\text{B.7})$$

id est

$$\sum_{pq} \langle p | \hat{u} | q \rangle \{\hat{p}^\dagger \hat{q}\} \{\hat{a}^\dagger \hat{i}\} |0\rangle. \quad (\text{B.8})$$

There are four different terms arising from this expression, depending on whether p and q represents particles or holes. Beginning with a *particle-particle* term,

$$\begin{aligned} \langle b | \hat{u} | c \rangle \{\hat{b}^\dagger \hat{c}\} \{\hat{a}^\dagger \hat{i}\} |0\rangle &= \langle b | \hat{u} | c \rangle \{\hat{b}^\dagger \hat{c} \hat{a}^\dagger \hat{i}\} |0\rangle + \langle b | \hat{u} | c \rangle \{\hat{b}^\dagger \hat{c} \hat{a}^\dagger \hat{i}\} |0\rangle \\ &= \langle b | \hat{u} | c \rangle \hat{b}^\dagger \hat{a}^\dagger \hat{i} \hat{c} |0\rangle + \langle b | \hat{u} | c \rangle \delta_{ac} \{\hat{b}^\dagger \hat{i}\} \\ &= 0 + \langle b | \hat{u} | c \rangle \delta_{ac} |\Phi_i^a\rangle, \end{aligned} \quad (\text{B.9})$$

giving non-zero contributions of the type

$$\langle b | \hat{u} | a \rangle \{\hat{b}^\dagger \hat{a}\} |\Phi_i^a\rangle = \langle b | \hat{u} | a \rangle |\Phi_i^b\rangle. \quad (\text{B.10})$$

We can draw a graphical representation of this contraction process,

$$\begin{array}{c} \langle b | \hat{u} | c \rangle \{\hat{b}^\dagger \hat{c}\} : \times \text{---} \begin{array}{c} \text{b} \nearrow \\ \text{c} \searrow \end{array} \\ \rightarrow \begin{array}{c} \text{a} \uparrow \quad \text{i} \downarrow \\ \hline \text{---} \end{array} \end{array} \quad \rightarrow \quad \begin{array}{c} \text{b} \nearrow \\ \text{c} \searrow \\ \text{---} \delta_{ac} \text{---} \\ \text{a} \uparrow \quad \text{i} \downarrow \\ \hline \text{---} \end{array} \quad \rightarrow \quad \begin{array}{c} \text{b} \uparrow \quad \text{i} \downarrow \\ \text{---} \bullet \text{---} \\ \text{a} \uparrow \\ \hline \text{---} \end{array} \quad (\text{B.11})$$

Now, let's consider a *hole-hole* term acting on the same single-excited Slater determinant,

$$\begin{aligned} \langle j | \hat{u} | k \rangle \{\hat{j}^\dagger \hat{k}\} \{\hat{a}^\dagger \hat{i}\} |0\rangle &= \langle j | \hat{u} | k \rangle \{\hat{j}^\dagger \hat{k} \hat{a}^\dagger \hat{i}\} |0\rangle + \langle j | \hat{u} | k \rangle \overline{\{\hat{j}^\dagger \hat{k} \hat{a}^\dagger \hat{i}\}} |0\rangle \\ &= -\langle j | \hat{u} | k \rangle \{\hat{k} \hat{a}^\dagger \hat{i} \hat{j}^\dagger\} |0\rangle + \delta_{ij} \langle i | \hat{u} | k \rangle \{\hat{k} \hat{a}^\dagger\} |0\rangle \\ &= 0 - \delta_{ij} \langle i | \hat{u} | j \rangle \{\hat{a}^\dagger \hat{k}\} |0\rangle \\ &= -\delta_{ij} \langle i | \hat{u} | j \rangle |\Phi_k^a\rangle, \end{aligned} \quad (\text{B.12})$$

meaning we are only left with non-zero contributions of the type,

$$\langle i | \hat{u} | j \rangle \{ \hat{i}^\dagger \hat{k} \} | \Phi_i^a \rangle = - \langle i | \hat{u} | k \rangle | \Phi_k^a \rangle. \quad (\text{B.13})$$

One can make a diagrammatic representation of this contraction as well,

$$\langle b | \hat{u} | c \rangle \{ \hat{b}^\dagger \hat{c} \} : \times \text{---} \text{---} \text{---} \rightarrow \text{---} \text{---} \text{---} \rightarrow \text{---} \text{---} \text{---} \quad (\text{B.14})$$

Next, we look at the *particle-hole* term,

$$\begin{aligned} \langle b | \hat{u} | j \rangle \{ \hat{b}^\dagger \hat{j} \} \{ \hat{a}^\dagger \hat{i} \} | 0 \rangle &= \langle b | \hat{u} | j \rangle \{ \hat{b}^\dagger \hat{j} \hat{a}^\dagger \hat{i} \} | 0 \rangle \\ &= \langle b | \hat{u} | j \rangle \hat{a}^\dagger \hat{b}^\dagger \hat{j} \hat{i} | 0 \rangle \\ &= \langle b | \hat{u} | j \rangle | \Phi_{ij}^{ab} \rangle, \end{aligned} \quad (\text{B.15})$$

with no contraction in this case. This expression is represented by

$$\quad \quad \quad (\text{B.16})$$

showing the resulting determinant is $| \Phi_{ij}^{ab} \rangle$. Holes and particles joined at the same vertex, on the same path, are in the same vertical position in the excited Slater determinant. This representation may appear to leave out the cases where $i = j$ and/or $a = b$, but these diagrams will give a vanishing Slater determinant.

The *hole-particle* term is

$$\begin{aligned} \langle j | \hat{u} | b \rangle \{ \hat{j}^\dagger \hat{b} \} \{ \hat{a}^\dagger \hat{i} \} | 0 \rangle &= \langle j | \hat{u} | b \rangle \{ \hat{j}^\dagger \hat{b} \hat{a}^\dagger \hat{i} \} | 0 \rangle + \langle j | \hat{u} | b \rangle \{ \hat{j}^\dagger \hat{b} \hat{a}^\dagger \hat{i} \} | 0 \rangle \\ \hat{U}_N = &+ \langle j | \hat{u} | b \rangle \{ \hat{j}^\dagger \hat{b} \hat{a}^\dagger \hat{i} \} | 0 \rangle + \langle j | \hat{u} | b \rangle \{ \hat{j}^\dagger \hat{b} \hat{a}^\dagger \hat{i} \} | 0 \rangle \\ &= \delta_{ij} \delta_{ab} \langle j | \hat{u} | b \rangle | 0 \rangle = \langle i | \hat{u} | a \rangle | 0 \rangle, \end{aligned} \quad (\text{B.17})$$

which is represented by

$$\quad \quad \quad (\text{B.18})$$

which shows that the result of the operation involved the vacuum state.

The full one-body operator becomes,

$$\begin{aligned}
 & \sum_b \text{Diagram 1} + \sum_j \text{Diagram 2} + \sum_{bj} \text{Diagram 3} + \text{Diagram 4} \\
 & \langle b | \hat{u} | a \rangle | \Phi_i^b \rangle \quad - \langle i | \hat{u} | j \rangle | \Phi_j^a \rangle \quad \langle b | \hat{u} | j \rangle | \Phi_{ij}^{ab} \rangle \quad \langle i | \hat{u} | a \rangle | 0 \rangle
 \end{aligned} \tag{B.19}$$

The diagrams are as follows:

- Diagram 1:** A vertical line with a double underline at the bottom. A dot is on the line. An arrow labeled 'i' points down from the top. An arrow labeled 'a' points up from the bottom. A dashed line with an 'X' at the end connects the dot to the right.
- Diagram 2:** A vertical line with a double underline at the bottom. A dot is on the line. An arrow labeled 'j' points down from the top. An arrow labeled 'i' points up from the bottom. A dashed line with an 'X' at the end connects the dot to the left.
- Diagram 3:** A vertical line with a double underline at the bottom. A dot is on the line. Two arrows, labeled 'b' and 'j', point down from the top. An arrow labeled 'i' points down from the top. An arrow labeled 'a' points up from the bottom. A dashed line with an 'X' at the end connects the dot to the left.
- Diagram 4:** A triangle with a double underline at the bottom. The left side has an arrow labeled 'i' pointing down. The right side has an arrow labeled 'a' pointing down. The top side has a dashed line with an 'X' at the end.

Anhang C

2D Coulomb elements

Implementation of two-body matrix elements for the two-dimensional quantum dots[2]. Note that Anisimovas and Matulis uses the chemist's convention $\langle ij|\hat{u}|lk\rangle$ which is $\langle ij|\hat{u}|kl\rangle$ in the physicist's notation. That is, the last two indices are interchanged.

```
def coulomb_ho(n_i, m_i, n_j, m_j, n_l, m_l, n_k, m_k):
